ABSTRACT

The Navy is increasingly using advanced Unmanned Air Vehicles (UAVs) to perform critical missions. UAVs have grown in capability, while the Navy's underlying Command and Control structure has changed little to take advantage of the advances in technology. While UAVs are rapidly developing the potential to be effective combat tools, learning how to utilize this potential in an integrated Command and Control environment is hampered by a lack of UAV connectivity.

This thesis develops a methodology for using UAV telemetry data packets to inject tracks of the UAV into a Command and Control system such as the Global Command and Control System (GCCS), and provide near-real-time imagery delivery from the UAV to tactical end users via a network such as the Secret Internet Protocol Router Network (SIPRNET). Focus is on the development of a proof-of-concept system utilizing the Naval Postgraduate School's Systems Technology Battle Lab (STBL) and the Center for Interdisciplinary Remotely-Piloted Aircraft Studies (CIRPAS) Altus UAV. Through the developing of this system, the Altus UAV can serve as a research tool for further development of Command and Control doctrine for operational UAVs.

I. INTRODUCTION

A. OVERVIEW

This thesis examines the technical aspects of implementing a UAV track injection and imagery presentation system (UTI^{2}PS). The technology of UAVs is developing quicker than the underlying "intelligence machine" and in fact, is outpacing the advancement of C4I systems. While the bandwidth capacity and technical capability of C4I systems is increasing, the connectivity necessary for UAVs has yet to be incorporated. This thesis provides a technical demonstration of how UAVs can provide positional and imagery data to the end user via current command and control systems such as the Global Command and Control System (GCCS), and communication means such as the Secret Internet Protocol Router Network (SIPRNET). Common off the shelf (COTS) hardware and software as well as open standards are utilized where possible.

B. PURPOSE OF RESEARCH

The purpose of this thesis is to develop a low cost, COTS, near-real-time methodology for getting telemetry and imagery from UAVs to tactical end users. An architecture will be identified which will provide connectivity from a UAV through the Ground Control Station controlling it, to end tactical users via the Global Command and Control System and SIPRNET. High levels of availability, scalability, compatibility, and flexibility will be achieved by using a TCP/IP network-based architecture to as great an extent as possible. This thesis will also demonstrate the technical feasibility of such a proposed architecture by development of a proof-of-concept implementation.

C. SCOPE OF RESEARCH

This research presents the requirements, architectural design, and a proof-of-concept implementation of a prototype system to inject UAV telemetry and imagery information into a command and control system. A proof-of-concept prototype implementation illustrates the conceptual as well as technical viability of the concepts

1

presented within this thesis. This proof-of-concept demonstration sets the stage for further refinement of this technology, and provides a valuable research tool for the evaluation of UAV Command and Control techniques that will potentially become future doctrine.

The following research questions are addressed:

1. What are the requirements for a UAV track injection and imagery presentation system (UTI^{2}PS)?
2. What is the appropriate architecture for such a system?
3. How can telemetry data be extracted from the UAV Ground Control Station RS-422 port?
4. How can imagery data be captured and encoded at the Ground Control Station?
5. How can telemetry and imagery data be transmitted to the NPS Systems Technology Battle Lab (STBL) or other SIPRNET insertion points from remote locations?
6. How can ANSI/IEEE standard 754 telemetry data packets be converted into Over The Horizon Targeting Gold (OTG) format for injection into Command and Control Systems?
7. How can OTG messages be processed to create a track within the Global Command and Control System?
8. How can imagery, both motion and still, be transferred, stored, and displayed over a TCP/IP network such as the Secret Internet Protocol Router Network (SIPRNET)?

These research questions are answered within this thesis through the development of a proof-of-concept demonstration.

D. THESIS ORGANIZIATION

This thesis is organized as follows: Chapter II further defines the problem statement. Chapter III describes the system Architecture starting at a high level. Chapter IV then provides a detailed discussion of the telemetry methodology as Chapter V does for the imagery methodology. Chapter VI describes the implementation details of the proof-of-concept demonstration and the results obtained. Finally, Chapter VII presents research conclusions and recommendations for further work. Appendices are included

which contain program code developed as part of the proof-of-concept implementation deemed significant.

II. PROBLEM STATEMENT

A. INTRODUCTION

This chapter outlines a set of UAV command and control challenges addressed in this thesis, and the associated limitations in current UAV telemetry and imagery dissemination that must be overcome in order to solve them. It then introduces the focus for the system that will be developed within this thesis to demonstrate means to overcome the data dissemination limitations.

B. COMMAND AND CONTROL

The ability to make timely decisions is a key objective of the command and control process. As our knowledge about a situation increases, so does the ability to make sound decisions. UAVs can provide critical components of the overall tactical picture. However, in order to maximize the benefits UAVs can provide, new command and control structures must be developed, which will require the application of new technology for the dissemination of telemetry and imagery from UAVs.

> Current UAV systems were born largely from advanced technology demonstration projects. They were designed more to validate and test the technology than to operate in standardized command and control environments. While they proved successful operationally, as demonstrated by the Pioneer during the Gulf War and the Predator in Bosnia, they were tasked in a very narrow capacity with dedicated command and control, limited image dissemination, and restricted inter-connectivity.

> In the Navy, operational UAV doctrine is based almost entirely on the Pioneer system. The Pioneer UAV has a narrow mission and a corresponding limited operational doctrine. This doctrine does not translate to the increased capabilities and expanded scope the Navy will enjoy with VTUAVs. Furthermore, the Navy must expand its doctrine to encompass HAE UAVs, since these will feed data into naval C4I systems.

The Navy's IT-21 and JV 2010 policy statements also indicate a paradigm shift towards increasing inter-connectivity and the concept of Network-centric Warfare. In this vision, data from all sensors is available across the network for utilization by war fighters that can parlay a narrow requirement for information into a tactical advantage. The growth in intelligence gathered by UAVs underscores the requirement to integrate them into the C4I environment.

The existing UAVs are all independent systems. They do not inter-connect easily with command and control systems, which isolates them from the lower echelons that need the information. The information is strictly in one form: processed data that is derived from the sensor data. This information must be filtered through a rigid dissemination process that limits the inherent flexibility of UAVs. Imagery to the tactical warfighter and real-time tracks will be important for modern UAVs." [Ref 1: pp. 23-24]

The operational objective is to get UAV positional information and imagery to the war fighter. The war fighter is anyone from the troops in the trenches who are fighting the battle, to the commanders at all levels who are planning for the successful outcome of the operation. Thus there is a need to provide real time information to enhance the war fighters situational awareness.

1.   Track Injection

The capability to directly interface with the Global Command and Control System (GCCS), therefore allowing full awareness of a UAV's position (and UAV generated tracks) through track symbology on the Common Operating Picture (COP), will enable track de-confliction and allow commanders to assess utilization and provide direction of UAVs. Currently capabilities do not exist to detect and track a UAV, and to hold the UAV track data beyond organic sensors (OTH), without relying on a commander's organic assets such as radar.

According to HAE UAV CONOPS, the battle group does not have JMCIS track information on the HAE UAVs to de-conflict them from radar tracks. The HAE UAV CONOPS does not address the dissemination of real-time air vehicle track information from the ground control element to the fleet. Therefore, the battle group must assume that any airborne track is hostile if it does not hold a JMCIS track to merge it with. [Ref 1: p. 28]

Only with real-time track information will commanders be able to monitor the position of UAVs, and effectively integrate them into the war fighter's forces in order to properly employ them.

2. Imagery Dissemination

The UAV imagery dissemination pipeline begins at the air vehicle sensor and, for the purposes of this thesis, ends with the end user. Current UAV image dissemination systems are essentially stove-piped systems, with little or no mechanism to deliver imagery to end tactical users in a timely manner.

Currently, high value units (HVUs) may have the capability to receive imagery time-late, but other ships within a battle group probably do not because the capability for broadband connectivity between ships is limited, and will not support direct broadcast reception of live video feeds. Thus currently a destroyer firing on a target can not use UAV imagery directly to make fire corrections.

However, raw imagery from a UAV is not enough. Imagery should be processed to include vital telemetry information such as location, orientation, time, date and other kinematics data.

Raw imagery, even when comprehensive and unquestionably accurate, is of little use to the war fighter. It may be a wonderfully clear photographic image of some location, but without additional, vital information, such as the location of the photo, its orientation to true north, and its time and date of origin, the image might be useless. [Ref 2: p. 21]

C. FOCUS FOR SYSTEM DESIGN

1. Center for Interdisciplinary Remotely-Piloted Aircraft Studies

The Center for Interdisciplinary Remotely-Piloted Aircraft Studies (CIRPAS) is an independent research program, administratively associated with the Naval Postgraduate School (NPS), that provides UAV flight services to the research, development, test and evaluation communities. CIRPAS has hanger, maintenance and administrative spaces at the Marina Municipal Airport (formerly Fort Ord's Frizsche Field), located close to NPS. They also have established an unmanned aircraft base of operations at Camp Roberts, CA, an Army National Guard base located approximately 80 miles south of the Marina facility. The UAV base of operations allows unmanned vehicle operations in restricted airspace over Camp Roberts and nearby Ft. Hunter-Liggett. [Ref 3]

Along with the Pelican, UV-18A Twin Otter, and recently acquired Preditors, CIRPAS operates the Altus UAV (Figure 2.1), which was developed by General Atomics, and is similar to the Predator UAV. The Altus is used to support Atmospheric Radiation Measurement (ARM) for the Department of Energy's Sandia National Labs. Because of an agreement with the DoE, CIRPAS is able to provide the services of the Altus to other users when not supporting the ARM experiment. As a result, the Altus is used as a test bed for various developmental payloads, and serves as a surrogate for operational UAVs. Thus the Altus provides an excellent test bed for the development of a UAV track injection and imagery presentation system.
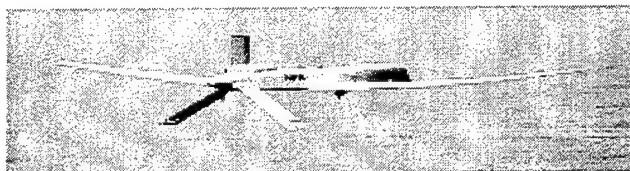

Figure 2.1: Altus UAV

Imagery and kinematic data from the Altus UAV is currently down-linked via C-Band line-of-sight (LOS) to a General Atomics developed Ground Control Station (GCS) which provides aircraft control functions (Figure 2.2). The GCS has redundant pilot / payload operating stations and is housed in a rugged 16-ft long trailer (Figure 2.3). At the GCS, imagery and kinematic telemetry are archived onto tape for future analysis and review. The imagery includes video from a forward-facing camera used to remotely pilot the UAV, and can also include video from a payload camera. The kinematic telemetry includes all data necessary to monitor the UAV status, including oil pressure, prop RPM, servo temperature, GPS position, heading, altitude, and airspeed. This telemetry also includes all necessary components to create a track symbol of the UAV for insertion into the Common Operational Picture (COP).

Figure 2.2: Interior of Ground Control Station

Figure 2.3: Exterior of Ground Control Station

The missing components to enable the creation of tracks of the UAV are links between the Ground Control Station and the existing Global Command and Control System (GCCS) Common Operational Picture (COP) environment. The goal of this research is to develop these links and also demonstrate a means of presenting near-real-time imagery from the Altus UAV to the tactical war fighter via the Command and Control network, or SIPRNET.

2. Developed Methodology

Creating track symbology of the Altus within the GCCS, specifically on the Common Operating Picture (COP), requires several steps. Overall, the telemetry data must be captured at the GCS and converted into a format that can be injected into the GCCS. This will require converting the telemetry from General Atomics proprietary ANSI 754 format into a format that can be read into the GCCS track information database, such as Over The Horizon Targeting Gold (OTG) messages. Next these messages must be transmitted to a location where they can be injected into the GCCS. Finally, these messages will yield the track symbology for the Altus UAV displayed on

the COP, and although not part of this thesis effort, tracks detected by the UAV since that kinematics data is available from the UAV telemetry as well.

Providing near-real-time Altus imagery requires first capturing the live video from the GCS, and then converting it into a standardized digital format. The digitized imagery then needs to be transmitted to a server for archival and subsequent presentation to clients.

D. SUMMARY

The thesis examines the technical aspects of UAV telemetry and imagery dissemination necessary to enable the command and control mechanisms required to effectively leverage the additional capabilities presented by the proliferation of UAVs.

The primary goal of this research is to develop a proof-of-concept implementation of a system that will inject UAV telemetry information into the Global Command and Control System (GCCS) Common Operational Picture (COP), providing real-time UAV positional information to tactical war fighters. An additional goal is to develop a system that will provide imagery from UAVs to tactical war fighters in near-real-time. The CIRPAS Altus UAV will be used as a test-bed for the development of such a system, and can subsequently be used as a research tool for the evaluation of evolving UAV Command and Control doctrine.

III. SYSTEMS ARCHITECTURE

A. INTRODUCTION

This chapter presents the UAV Track Injection and Imagery Presentation System (UTI²PS) architectural model based on the design goals presented in the prior chapter. The goal is to design a system that will provide a subset of the telemetry and imagery data from the UAV to the tactical end user in near real time.

B. THE BIG PICTURE

The function that UTI²PS must perform is to act as an interface between the UAV and tactical end user, providing telemetry data to indicate where the UAV is currently located, and imagery data directed from the UAV payload camera. It is desirable to make this interface between the UAV sensor and tactical war fighter as simple as possible, thus shortening the sensor-to-shooter loop. Ideally such a system would consist of the UAV down- linking positional information and imagery data via a wireless network directly to the tactical end user as shown in Figure 3.1. Due to limitations in current UAV technology, this is not possible, so alternative means must be identified.

UAV

Kinematics &
Imagery Data

Cockpit

Fleet

Field
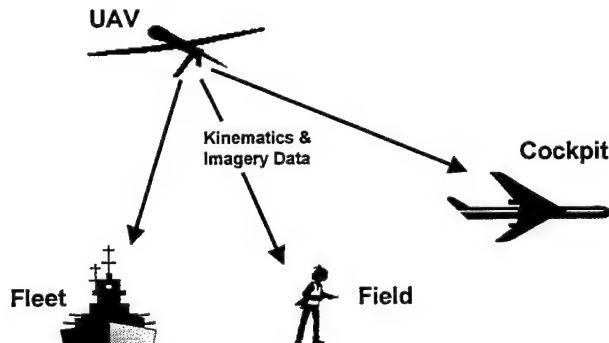

Figure 3.1: Ideal UAV Data Dissemination

Since it is not possible to retrieve data directly from a UAV such as the Altus, which utilizes C-Band LOS communications to a Ground Control Station (GCS), the UTI²PS system must extract the necessary telemetry and imagery data from this intermediate data collection source before it is provided to tactical end users via the C2 net or SIPRNET. This is illustrated in Figure 3.2 below:
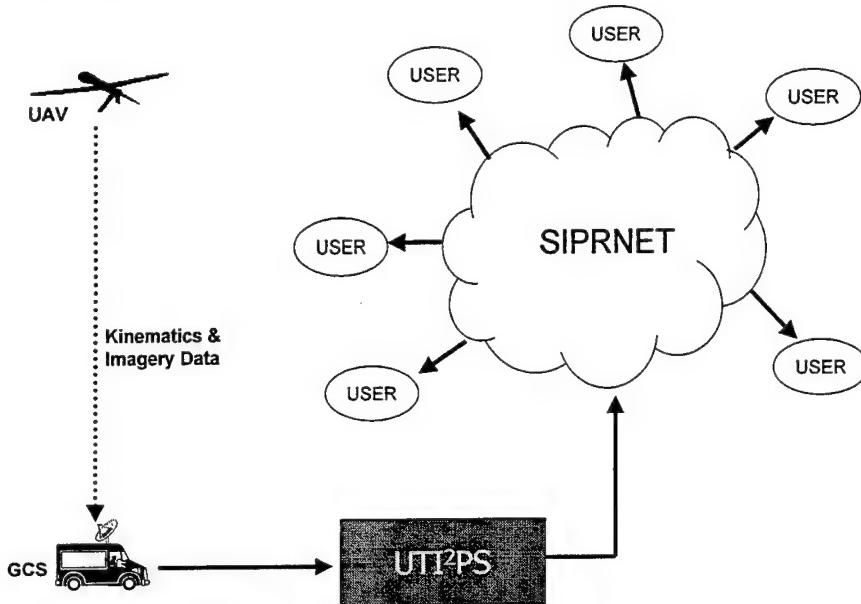

Figure 3.2: UAV Data Dissemination Using UTI²PS

C.   UTI²PS ARCHITECTURE

UAV telemetry data and video imagery is fed into the UTI²PS system from the GCS. The telemetry data is converted into OTG messages, which are the primary message format for Tactical Data Processor (TDP) information exchange and fully supported by the Global Command and Control System (GCCS).

Imagery from the GCS is feed into the UTI²PS system and split into two separate feeds to allow for the encoding of a live video stream, as well as the capturing of still digital images. It is desired to provide both streaming video and still imagery because this will best accommodate the perceived needs of the end user, while allowing the users

14

to manage bandwidth requirements. Providing high-resolution full-motion streaming video requires high bandwidth rates, which are currently not available to most tactical end users. Thus, it was decided that moderate resolution streaming video would be sufficient for end users if a means of providing higher-resolution still imagery for targets of interest could still be provided via an alternative means. Since moderate resolution streaming video, with occasional still digital images of high quality, can be provided using less bandwidth than would be required for high-quality full-motion video, this is a logical choice. If bandwidth to the end user is not available for providing even moderate quality streaming video, or it is deemed unnecessary, only the low bandwidth still imagery need be provided.

When still images are captured, the latest telemetry data indicating time and location of fix is also captured and saved to a database along with the still image. In addition, a kinematics-based OTG message is generated that also specifies the location of the image. Still images can then be retrieved from this database as desired by time, location, or track number.

Near real-time imagery is provided to end tactical users by a steaming media server via the SIPRNET or via the Global Broadcast System (GBS). Still imagery is retrieved from a database repository and provided to end-users over the SIPRNET from a web server. Positional data of the UAV is provided by a symbol on the Global Command and Control System (GCCS) Common Operating Picture (COP), which is generated by injecting OTG messages into a GCCS gateway, and broadcasting to clients over the SIPRNET. Figure 3.3 illustrates the flow of imagery and data from the UAV to the end user by means of the UTI²PS Architecture.
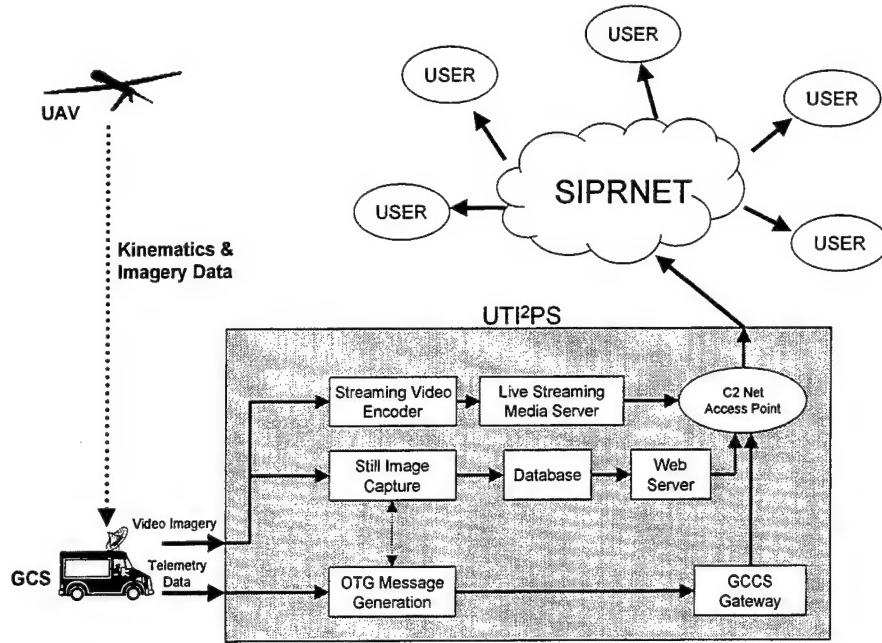

Figure 3.3: UTI²PS Architecture

D. PROOF-OF-CONCEPT ARCHITECTURE

For purposes of this thesis, a proof-of-concept implementation of UTI²PS was designed specifically to provide connectivity between the Altus UAV and the GCCS COP via the Systems Technology Battle Lab (STBL) at Naval Postgraduate School (NPS). Figure 3.4 illustrates the flow of data from the UAV to the GCS via C-Band LOS, then to the NPS STBL on a modem connection over POTS or ISDN, and finally out to end users via the SIPRNET.
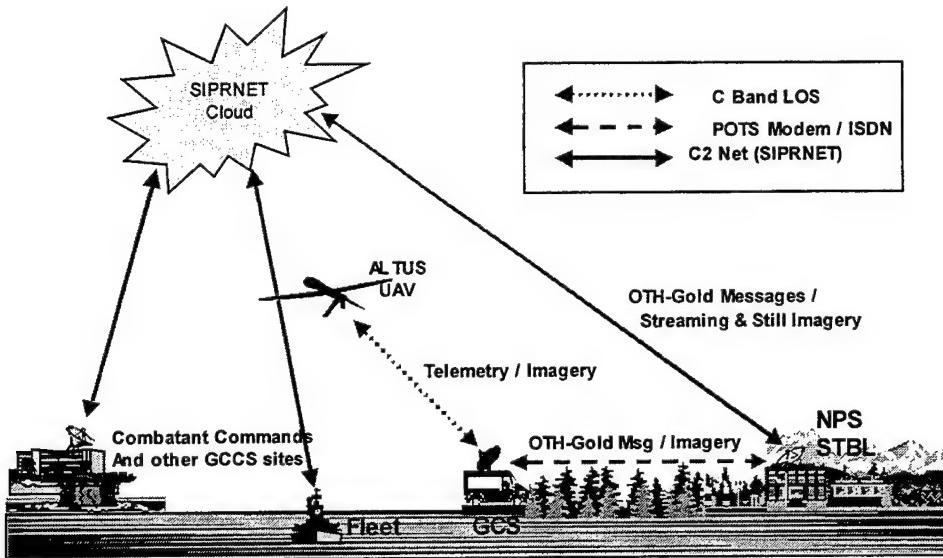

Figure 3.4: UTI²PS Proof-of-Concept Architecture

Figure 3.5 provides a more detailed look at the architecture for implementation of the proof-of-concept. From the GCS, digital telemetry data is transferred into a computer called the GCS Processor via an RS-422 serial interface. Two analog NTSC video feeds containing analog NTSC imagery from the UAV payload camera are also downloaded to the GCS Processor via the GCS. The GCS Processor converts the digital telemetry data into OTG messages, encodes one of the analog video feeds into a digital video stream, and allows for digital capture of still images from the other analog video feed.

Data containing the digital imagery and OTG messages is then transferred from the GCS site to the STBL using TCP/IP and Remote Access Server over a POTS or ISDN modem connection. At the STBL lab, a Server stores still images in a database and provides them to clients as requested via a web server. This server also serves up the digitized video stream to clients, and forwards the OTG Messages to a GCCS gateway via an RS-232 serial interface. Clients within the STBL, or on the SIPRNET, will then receive a track of the UAV on the GCCS COP, and be able to access imagery from the UAV via a web browser and streaming media player.

17
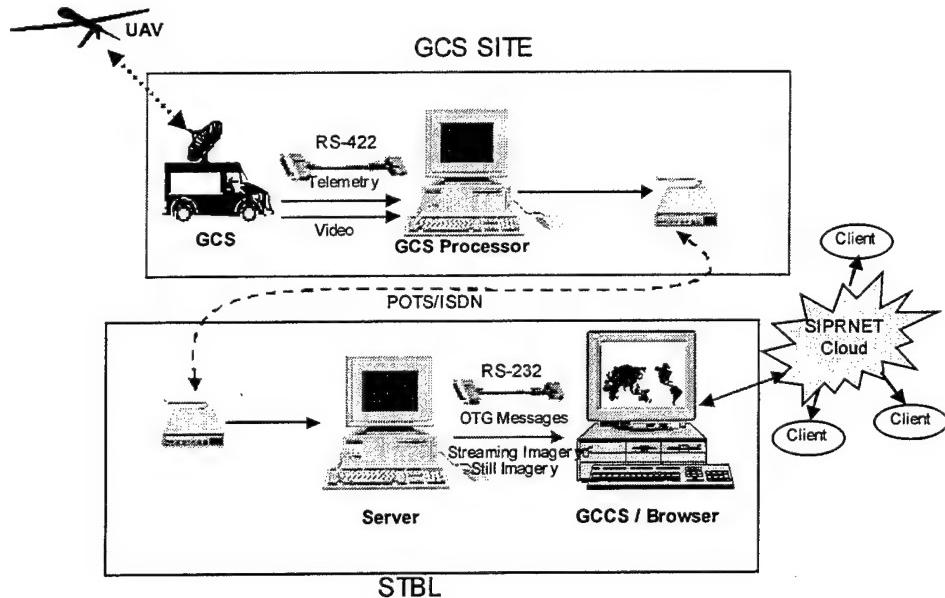

Figure 3.5: Detailed UTI^{2}PS Proof-of-Concept Architecture

E.   SUMMARY

The proof-of-concept UTI^{2}PS architecture utilizes common interfaces and open standards where possible, but still requires connection to proprietary non-networked systems via serial means. A network-centric system design where the UAV telemetry and imagery sensors could be directly linked to the GCCS command and control network would be more desirable due to the elimination of potential bottlenecks and single points of failure, but unfortunately this is not currently possible. The next two chapters provide more detail on the telemetry and imagery methodologies utilized in the proof-of-concept implementation.

IV. TELEMETRY METHODOLOGY

A. INTRODUCTION

The previous chapter discussed an overview of the system architecture. This chapter describes the methodology used in developing a system for capture, transmission, and presentation of Altus UAV telemetry data on the GCCS COP. This will enable GCCS users to view the UAV track when over the horizon (OTH). Previously the UAV was tracked using organic assets such as surface to air radar.

B. OVERVIEW

The goal of our digital telemetry research is to design a system that will convert a binary telemetry data packet received for the UAV into a formatted message suitable for injection into the GCCS. A diagram of the overall system architecture is illustrated below in Figure 4.1.
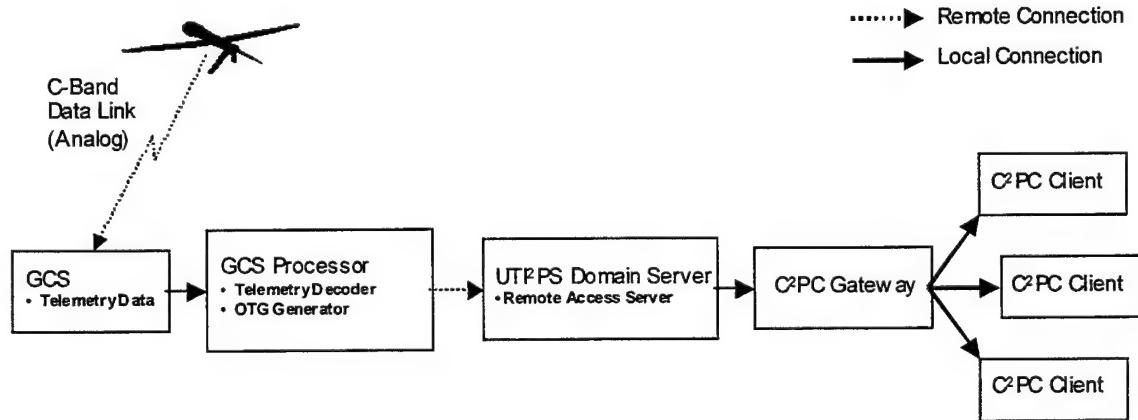

Figure 4.1: Basic UTIP²S Telemetry Block Diagram

19

The Altus UAV sends digital telemetry data to the Ground Control Station (GCS) using a line of sight C-band communications channel. At the GCS the data is processed for presentation to control and monitor the flight performance status of the UAV. Within the GCS there is the capability to feed a subset of the telemetry data to an external serial port. It is from this port that kinematic data such as latitude, longitude, altitude, course, and speed would be extracted.[1]

The telemetry data is fed to a processor co-located with the GCS where the binary data is converted from ANSI/IEEE-754 (single precision floating point format) to a formatted OTG message. This message is sent to a C^2PC Gateway via a remote access server using TCP/IP. The C^2PC Gateway is part of the Command and Control PC (C^2PC) suite, developed by Inter-National Research Institute (INRI), for Windows NT and is responsible for processing incoming OTG messages and updating the GCCS track information database. Clients that receive the appropriate GCCS feed will receive all messages that originate from the GCS.

C. OVER-THE-HORIZON TARGETING GOLD (OTG)

The Operational Specification for Over-The-Horizon Targeting GOLD...provides a standardized method for transmitting selected data between OTH-T systems and OTH-T support systems.... It is the primary message format for Tactical Data Processor (TDP) to TDP information exchange on the Officer in Tactical Command Information Exchange System (OTCIXS) and Tactical Data Information Exchange System (TADIXS). It is designed to be easily man readable for the non-TDP user. [Ref 4: p 1-1]

The OTG format is based on a set of message text formats that is fully described in the Operational Specification for Over-The-Horizon Targeting GOLD (OS-OTG) of 1 August 1997. Each line in the OTG message is limited to 69 characters in length and formatting rules must be carefully observed for the message to be processed by the C^2PC

---

[1] In the current software build, however, this data feed is disabled. The next software build, scheduled for April 1999, will restore this feature.

Gateway. Annex 3B (Contact Report) of OS-OTG is of particular interest in generating track data from the telemetry data packet and is discussed here. The selection of the OTG specification provides a standard message format for communicating proprietary telemetry data to GCCS users.

1. Contact Report

"The Contact Report message is used to exchange processed contact data and track management information between systems. It contains the identity, location, and movement of surface, subsurface, land, and air contacts." [Ref 4: p 3B-1] For our purposes, the only sets required for telemetry track injection into GCCS are MSGID; CTC and POS, which together comprise the contact segment; and ENDAT. Figure 4.2 shows a sample OTG contact report.

[MESSAGE HEADER]

MSGID/NCTSI/GOLD/0001/JUN
CTC/T7062/WICHITA-ROANOKE/////////09
POS/130500Z9/JUN/8500S3/00000W0
ENDAT

[END OF MESSAGE SEQUENCE]

Figure 4.2: Sample OTG Contact Report

a. *MSGID*

The MSGID set is the first formatted set of the OTG message and marks the beginning of formatted sets. The MSGID set uniquely identifies the message by originator of the message, type of message, and serial number.

b.   *Contact Segment*

The contact segment contains two sets: CTC and POS. The POS set must immediately follow the CTC set. Multiple contact segments are permitted with the OTG message but for our purposes only one segment is required. The CTC set contains description data and the POS set contains time and position data of the contact.

c.   *ENDAT*

The ENDAT set specifies the end of the OTG message and contains no data.

D.   TELEMETERY SOURCE AND STRUCTURE

Telemetry data sent from the UAV for output through the GCS external serial port is structured in a binary data packet and framed with data link escape codes. Occurrences of data link escape codes within the data must be repeated, a method known as stuffing. These packets are sent at a rate of 10 Hz. The port is configured as follows: 19,200 baud, 8 data bits, 1 stop bit, no parity, and no handshaking. [Ref 6]

1.   Packet Structure

Telemetry data from the GCS is structured in a 65-byte packet and is shown in Figure 4.3. The start of each packet is marked with the two-byte sequence <DLE><ID> while the end is marked with the sequence <DLE><ETX>. <DLE> is defined as hexadecimal 10 (ASCII code for Data Link Escape) and <ETX> is defined as hexadecimal 03 (ASCII code for End of Text). <ID> can be any character other than <DLE> or <ETX>. Packet data shall be any eight-bit value with the requirement that all data bytes equal to <DLE> must be sent twice. The receiving device must compress all occurrences of two <DLE> characters into one <DLE> data byte. [Ref 6]

Start		Telemetry Data	End	
<DLE>	<id>	61 Bytes (without stuffing)	<DLE>	<ETX>

Figure 4.3: Telemetry Data Packet

2. Data Structure

Telemetry data fields are described in Figure 4.4. The fields of interest are latitude, longitude, altitude, heading, and speed, as these are used to build the OTG message. Time of fix is not used and will be addressed as an area of future research.

Data Byte	Item	Source	Units
0-3	Latitude	Litton	Radians (+ North)
4-7	Longitude	Litton	Radians (+ East)
8-11	Altitude	Litton	Meters, MSL
12-15	Time of Fix	Litton	GPS Time
16-19	Airplane Pitch	Litton	Radians (+ Up)
20-23	Airplane Roll	Litton	Radians (+ Right wing down)
24-27	Airplane Heading	Litton	Radians
28-31	Latitude	General Atomics	Radians (+ North)
32-25	Longitude	General Atomics	Radians (+ East)
36-29	Altitude	General Atomics	Meters, MSL
40-43	Time of Fix	General Atomics	GPS Time
44-47	Airplane Pitch	Vertical Gyro	Radians (+ Up)
48-51	Airplane Roll	Vertical Gyro	Radians (+ Right wing down)
52-55	Airplane Heading	Magnetometer	Radians
56-59	True Airspeed		Knots
60	Reserved		

Figure 4.4: Telemetry Record Structure

3. Field Structure

The fields in the telemetry data packet are ANSI/IEEE 754 single precision floating point format. This format is defined as 32 bits long and consists of one sign bit,

23

an eight bit exponent, and a 23 bit mantissa. The first byte contains the sign bit and first seven bits of the exponent, the second byte contains the least significant bit of the exponent and seven most significant bits of the mantissa, while the remaining two bytes complete the mantissa. This format is shown in Figure 4.5. [Ref 6]
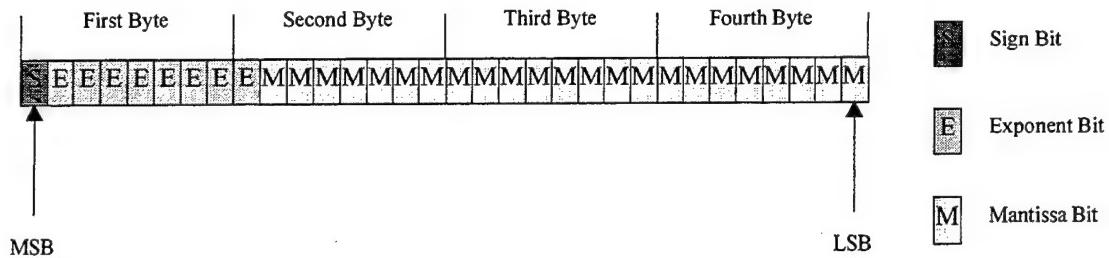

Figure 4.5: ANSI/IEEE 754 Single Precision Floating Point Format

E.   DATA CONVERSION

Telemetry data is sent from the GCS to the GCS processor for conversion to a format more suitable for injection into GCCS. Since data is sent from the GCS using RS-422, either an RS-422 port must be installed on the GCS processor or an RS-422 to RS-232 converter must be used. The serial port on the GCS processor must be configured as follows: 19,200 baud, 8 data bits, 1 stop bit, no parity, and no handshaking. The telemetry data packet is parsed and each element is converted from ANSI/IEEE-754 to ASCII text. The resulting text fields can then be used to generate messages for injection into the C^2PC Gateway

The OTG message generation process is shown in the accompanying flowchart (Figure 4.6), and is implemented using Microsoft's Visual C++. Visual C++ was selected because of its compatibility with commercially available ActiveX controls and the requirement to handle a wide variety of data types at the machine level. Appendix A contains the C++ code for converting the telemetry data into OTG messages.
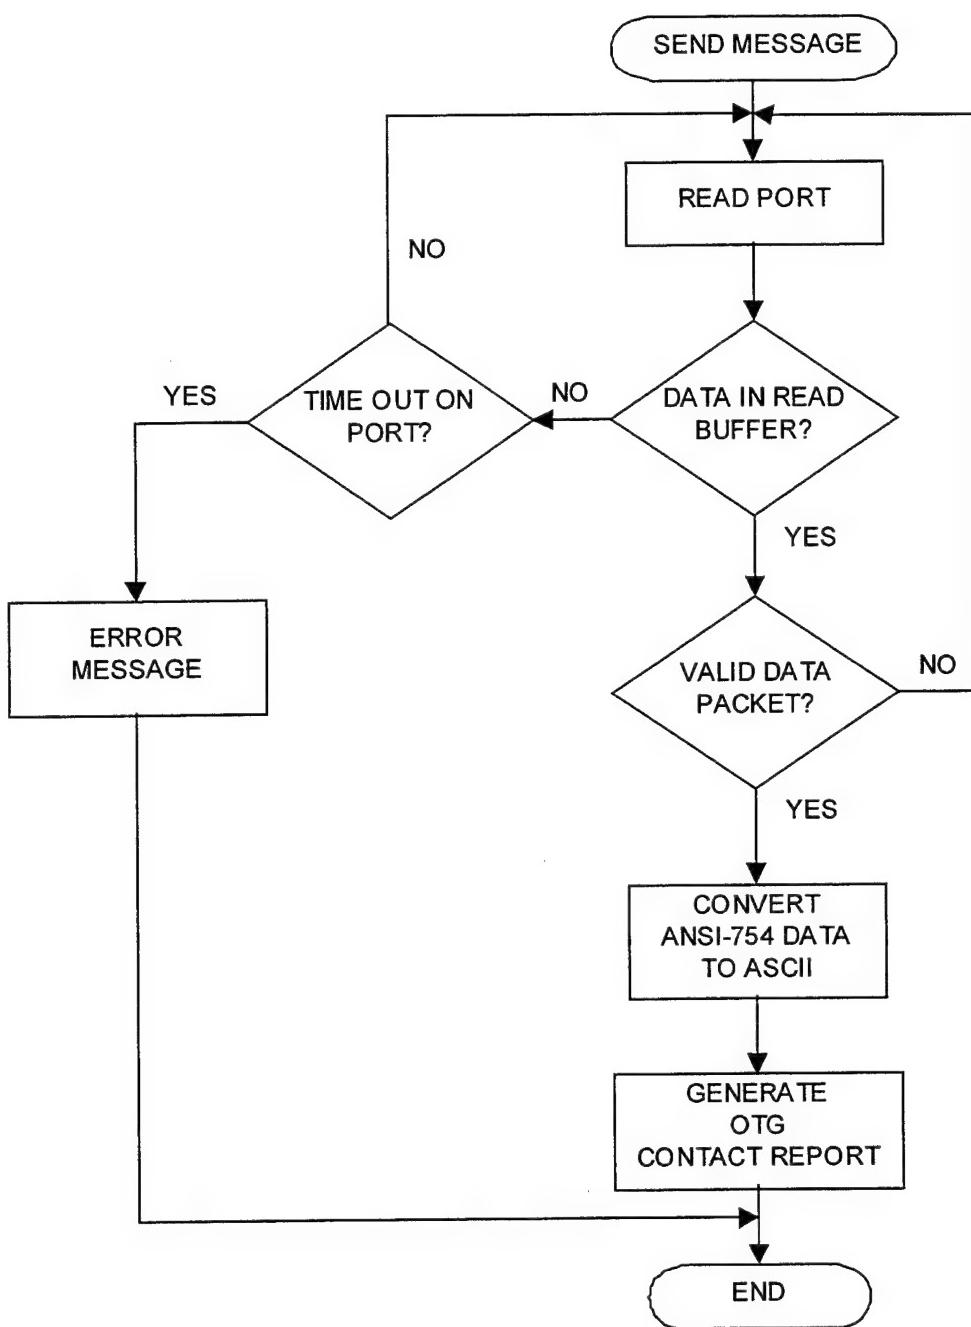

Figure 4.6: OTG Contact Report Generation Process

The conversion process starts when the user presses either the "Send Message" or "Auto Report" button on the user interface (Figure 4.7). The user interface, like the rest of the UTI²PS, was created by the authors. In the case of "Auto Report," a windows timer object is instantiated and every 20 seconds thereafter the process is run. The ASCII representation of the converted data and the OTG message are displayed on the interface. The "Capture Frame" and "Adjust Video" buttons are for capturing imagery and are discussed in Chapter V. See Appendix A for the code used to create the user interface.
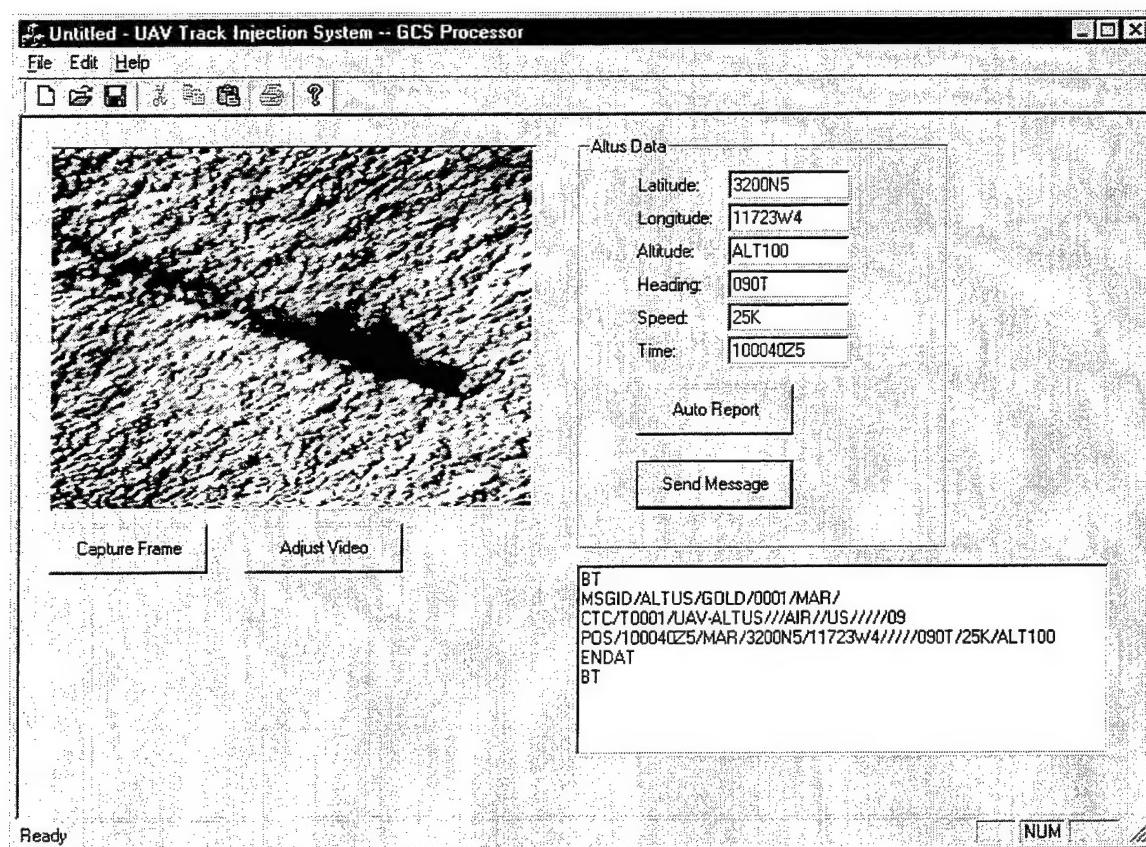

Figure 4.7: UTIPS User Interface

26

1. Receiving Data

Telemetry data packets are received through an RS-422 serial port installed on the GCS processor. Data received from this port is loaded into a buffer in memory. This buffer contains the data packet sent from the GCS, which must be checked for frame integrity and stuffing of <DLE> data bytes. If a framing error is detected processing stops and the process restarts when a valid frame is detected. If no data is received a time-out error, indicating communications problems, terminates processing.

2. Telemetry Data Conversion

The receive buffer is copied byte-for-byte using a function that strips the data link escape codes and compresses duplicate <DLE> data bytes into another buffer which is defined using a union of data types. By using a union the buffer containing the telemetry data can also be accessed using the structure data type associated with the union. Each field in the structure is converted to an ASCII equivalent text string, which is appropriately formatted for use with an OTG Contact Report and stored in another data structure that is passed to the message generation routine. [Ref 7]

a. Latitude

Latitude data from the GCS is measured in radians, with North expressed as a positive value and South as a negative value. The value must be converted to degrees and minutes and the sign expressed as an "N" or "S". A checksum is required.

b. Longitude

Longitude data from the GCS is measured in radians, with East expressed as a positive value and West as a negative value. The value must be converted to degrees and minutes and the sign expressed as an "E" or "W". A checksum is required.

c.   *Altitude*

Altitude data from the GCS is measured in meters. The value must be converted to feet. A checksum is not required.

d.   *Heading*

Heading data from the GCS is measured in radians. The value must be converted to degrees. A checksum is not required.

e.   *Air Speed*

Altitude data from the GCS is measured in knots. A checksum is not required.

3.   Other Data Conversion

The OTG contact report requires additional data in order to be successfully processed. These are reporting unit; message serial number; time and date; track number; class type and name; air, surface, or subsurface.

a.   *Reporting Unit*

Reporting unit is the name of the unit reporting the contact. As our intention is to design a self-reporting system, this is hard-coded as "ALTUS".

b.   *Message Serial Number*

Message serial number is a sequential order, for the calendar month, in which the message was sent. This number is stored as an integer in the GCS processor and is incremented each time a message is sent. The integer value must be converted to a formatted ASCII text string.

c.   *Time and Date*

Time and date is the time and date of the position report. The day of the month and time (in GMT) is extracted and converted to a formatted ASCII text string, which is concatenated with "Z", the time zone indicator for GMT, and a single digit checksum. The three-letter abbreviation for month is also extracted.

d.   *Track Number*

Track number is the local track number of Altus generated tracks. The Altus UAV will always report itself as track "T00001." Other tracks reported by Altus through the imaging sub-system are sequential beginning with "T00002" with an upper limit of "T99999."

e.   *Class Type and Name*

Class type and name is the unit class and unit name of the subject of the contact report. In the case of Altus UAV position reports this is hard-coded as "UAV-ALTUS". For other tracks this is hard-coded as "UNEQUATED-UNKNOWN".

f.   *Air, Surface, or Subsurface*

Air, surface, or subsurface specifies the contact as an air, surface, sub-surface contact. In the case of Altus UAV position reports this is hard-coded as "AIR". For all other tracks this is left blank.

4.   Message Generation

We now have the pieces required to generate an OTG message. A message template is initialized from string tables stored as an application resource. The dynamic data content is then loaded into the message template to complete the formatted OTG message.

a. *Template*

The OTG message template (Figures 4.8 and 4.9) is initialized each time a message is created. This is because the Altus UAV position report differs from the contact report generated by the UTI^{2}PS imagery subsystem.

```
MSGID/ALTUS/GOLD/<Serial>/<Month>
CTC/T0001/UAV-ALTUS///AIR//US/////09
POS/<Time>/<Month>/<Latitude>/<Longitude>/////<Heading>/<Speed>/<Altitude>
ENDAT
```

Figure 4.8: Altus UAV Position Report Template

```
MSGID/ALTUS/GOLD/<Serial>/<Month>
CTC/<Track Nr>/UNEQUATED-UNKOWN/
POS/<Time>/<Month>/<Latitude>/<Longitude>////////
ENDAT
```

Figure 4.9: Contact Report Template

b. *Dynamic Data*

The dynamic data is loaded into the message templates by inserting the data strings into their respective field positions. In the case of the imagery contact report the position data is that of the UAV itself rather than that of the image. However, the unique track number forces GCCS to create a new track on the COP. Actual contact position is left as an area for future research and is discussed further in Chapter VII.

5. Conversion Complete

With the generation of the OTG message, telemetry data conversion is complete. To be of use, the message must be routed to an OTH-T system that will provide track information to users with SIPRNET access to the GCCS database.

F.   MESSAGE ROUTING

The OTG contact report is wrapped in a TCP/IP packet with the destination address set to a host computer running a GCCS relay process. The relay process unwraps the OTG message and redirects it through a serial port connected to the C^2PC Gateway. The C^2PC Gateway in turn provides track information data to connected GCCS users. [Ref 8: p. 111]

1.   TCP/IP Transport

The OTG message is sent from the GCS processor to the GCCS relay using TCP/IP. Therefore the only requirement in sending the message is a network connection that supports TCP/IP which can be anything from a point-to-point dial-up connection to a RAS server to a satellite link.

Sending the OTG message using TCP/IP requires opening a connection to the GCCS relay specifying the host address and port number. The host address can be given as either the fully qualified domain name or the decimal dot address of the host. The port number is 2071. The combination of address and port provides a host socket address to which the message is sent. When the GCCS relay acknowledges the request, the OTG message is sent and the connection is closed. This is done using the CSocket class of the Microsoft Foundation Class for Visual C++ and is completely transparent to the user. [Ref 9]

2.   GCCS Relay

A relay is required because the GCCS will only accept OTG messages through a serial communications connection. The GCCS relay listens on port 2071 for OTG messages. When a message is received it is redirected to the serial port without error checking and passed on to the C^2PC Gateway for processing. Because a serial port is used to send data to the C^2PC Gateway it is possible to establish a one-way communications path between the relay host and the C^2PC Gateway. The GCCS relay

31

displays the OTG message as passes through the host (Figure 4.10). Appendix E contains the code used to generate the GCCS relay.
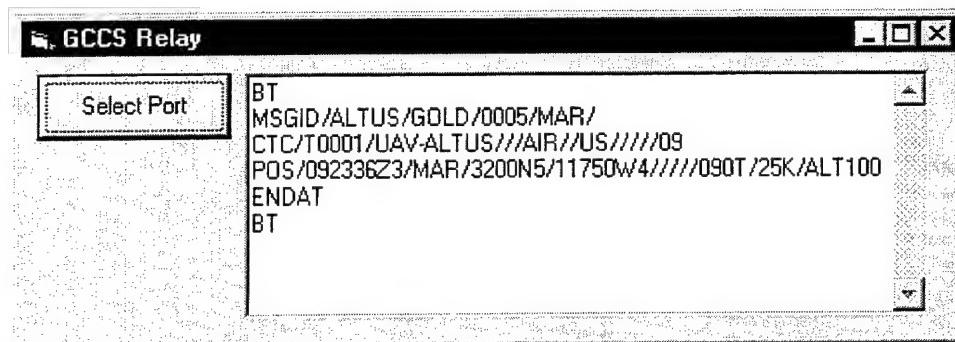

Figure 4.10: GCCS Relay Display

3.   C²PC Gateway

The C²PC Gateway receives OTG messages through a serial port. To enable the serial option on the C²PC Gateway GoldDB (Figure 4.11) must be selected as the data source. This is done from the Tools menu in the C²PC Gateway application. [Ref 8: pp. 112-113]
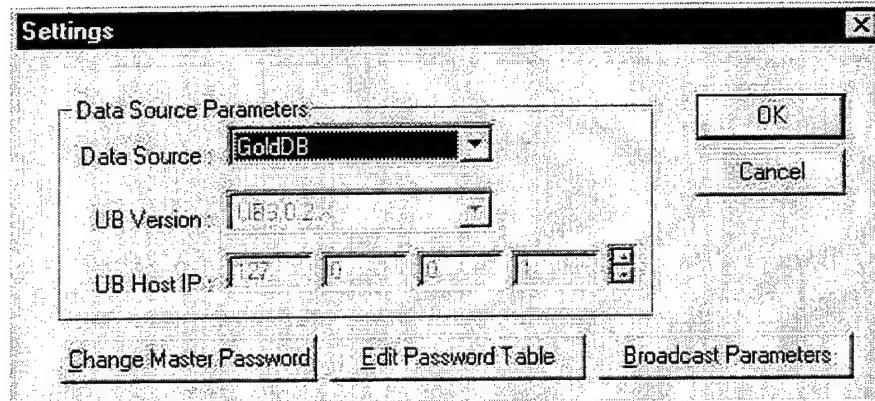

Figure 4.11: C²PC Gateway Settings Dialog

The serial port for the C²PC Gateway is controlled from the C²PC Serial application and must be configured to match the settings of the GCCS relay. Serial must

be running in order for messages to be processed by the C²PC Gateway. OTG messages will be displayed as they are received (Figure 4.12).

```
BT
MSGID/ALTUS/GOLD/0213/MAR/
CTC/T0001/UAV-ALTUS///AIR//US/////09
POS/100204Z7/MAR/3200N5/11649W1////090T/25K/ALT100
ENDAT
BT
```
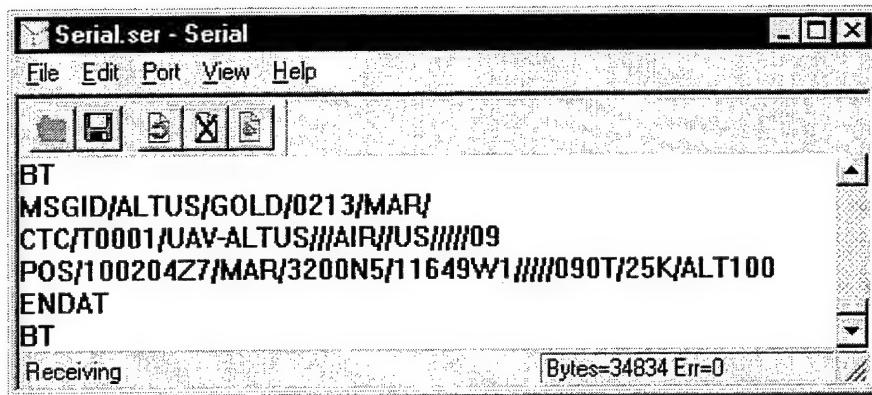

Figure 4.12: C²PC Serial Application

Telemetry processing is complete when the OTG contact report is received and processed by the C²PC Gateway.

G. GCCS COP DISPLAY

When an OTG message is processed by the C²PC Gateway the track information database is updated. The updated position (or new track) will be sent to GCCS clients and the COP refreshed (Figure 4.13).
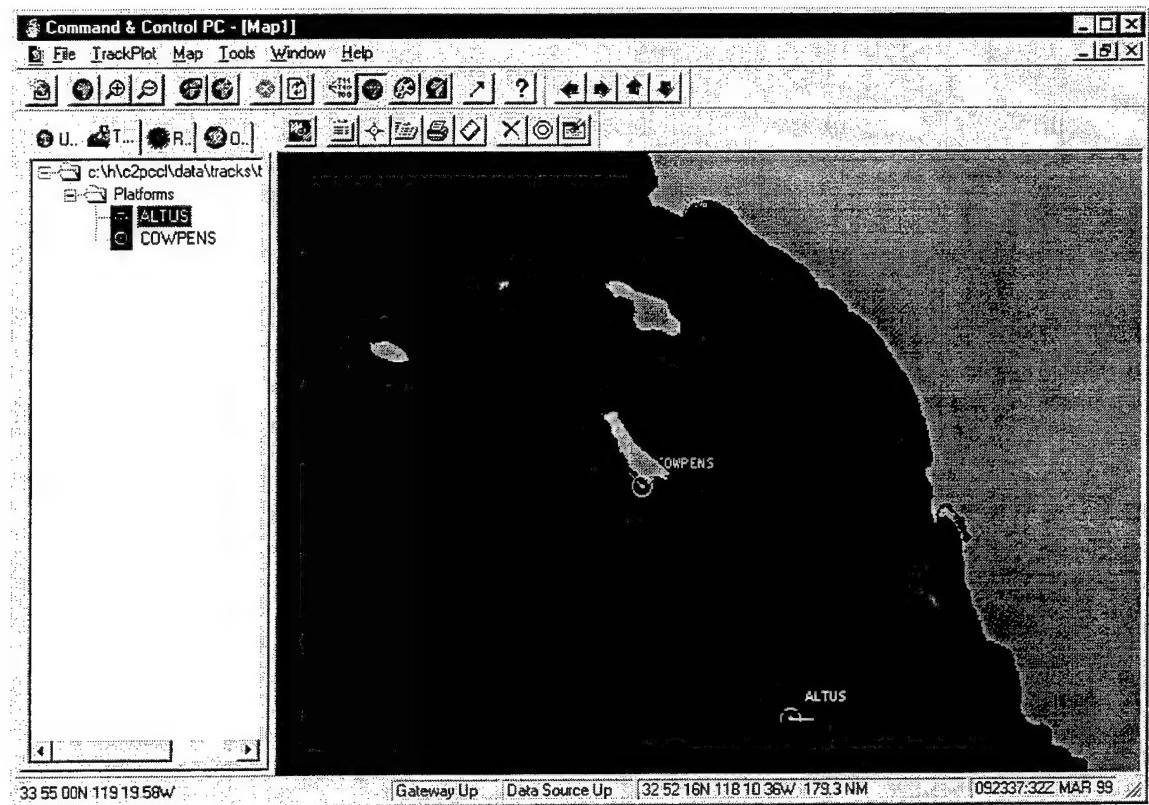

Figure 4.13: GCCS C²PC COP Display

V.   IMAGERY METHODOLOGY

A.   INTRODUCTION

The previous chapter discussed pivotal telemetry methodology, this chapter describes the methodology used to develop a system for the capture, transmission, and presentation of Altus UAV imagery data. Streaming digital video along with captured images in digital format will be provided to a web server, for viewing over the SIPRNET. In addition to the UAV kinematics track data provided for display on the GCCS COP, the GCCS user will also be able to view near-real-time digital imagery sent by the UAV.

B.   OVERVIEW

The goal of this area of research is to design a system using commonly available off the shelf (COTS) hardware and software that will provide for the seamless wide dissemination of near real time imagery from the Altus UAV. A diagram of the overall system architecture is illustrated in Figure 5.1 below.
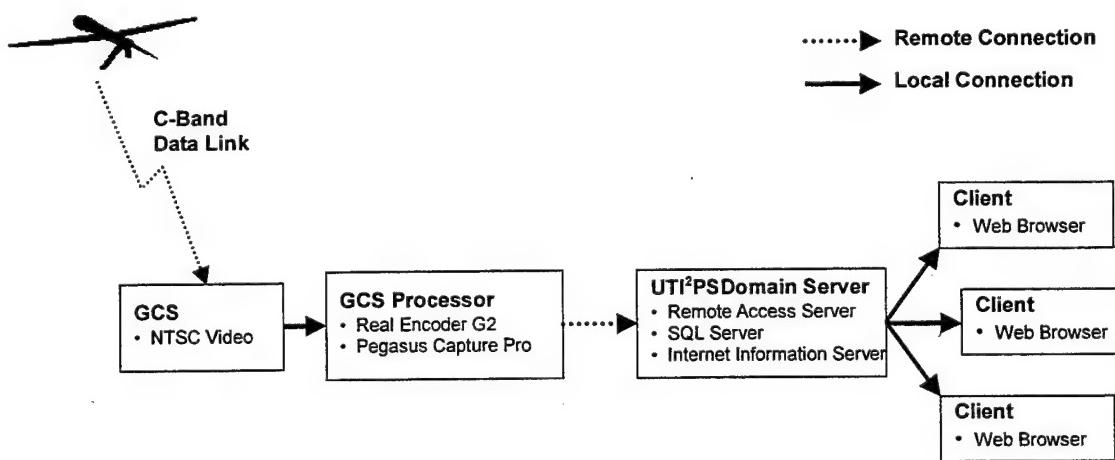

Figure 5.1: Basic UTI²PS Imagery Block Diagram

The Altus UAV transmits imagery from a payload camera to the Ground Control Station (GCS) via RF in NTSC analog format. From the GCS, this imagery is directly fed into a computer workstation located at the GCS site. This computer will be referred to as the GCS Processor. After the imagery is captured and processed by the GCS Processor, it is transmitted to a server at a SIPRNET access site that then inserts live streaming video and repository still imagery to any number of SIPRNET clients via a web browser interface.

The imagery interface between the GCS and remote processor is standard NTSC composite format video. After capture and encoding, digital imagery data is transmitted to the Server in TCP/IP packets over a modem connection. The Server then streams near-real-time imagery over a TCP/IP network to clients, and provides a database repository of still images which clients can remotely access via a web browser as desired.

C.   DATA SOURCE

The source of imagery is the Altus UAV payload camera. From the UAV, this imagery is transmitted via C-Band line-of-sight (LOS) to the GCS. This imagery is then provided in standard NTSC composite video format on jack J-11 of the GCS input/output panel. The GCS input/output panel is show in Figure 5.2.
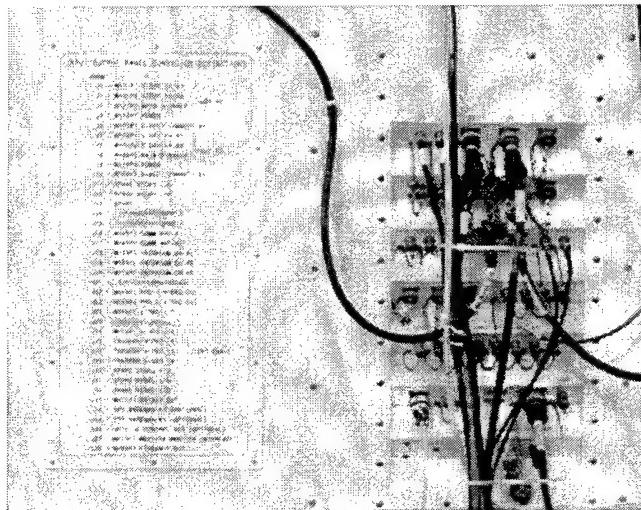

Figure 5.2: GCS Input / Output Panel

This source of imagery contains the raw imagery only, without any telemetry overlays showing position data for the imagery. Imagery with overlays showing telemetry data such as location, orientation to true north, and time & date is available on the CRT displays within the GCS. Providing imagery with these overlays would be possible by tapping off of the RGB inputs going into the CRT displays within the GCS. A tap from these RGB inputs could then be feed into a RGB to NTSC composite video converter and used as the imagery data source rather than the output from jack J-11.

Ideally, imagery data should be provided directly from the GCS, and even the UAV, in digital format such as JPEG. In general architectural engineering terms, the closer the processing is to the data source the better. This would eliminate the necessity to convert the imagery to NTCS, and then digital format as described in the following section. Based on current architecture though, this is not possible, necessitating the methodology used.

D.   IMAGERY ACQUISITION REQUIREMENTS

This section describes hardware and software requirements for acquiring imagery from the GCS for distribution on the network.

1.   Hardware Requirements

From the GCS, imagery is transferred in NTSC video format to a video capture device located in a computer workstation that digitizes and processes the video, and is thus referred to as the Remote Processor. The minimum recommended hardware requirements based on the software being utilized for imagery acquisition is a Pentium II-266 MHz computer with 64 Mbytes of RAM.

Because it is desired to provide a continuous live imagery stream from the UAV, while simultaneously capturing still imagery, two separate capture devices are utilized. The capture devices utilized are Osprey-100 Peripheral Component Interconnect (PCI) bus digital video capture cards. The Osprey-100 was chosen because of its advertised compatibility with the software being used for acquisition, and because multiple Osprey-

100 video capture cards can be installed in the same computer, preventing a requirement for separate remote processor workstations. Both video capture cards are feed with the same standard NTSC composite video source from the GCS, by splitting the signal and feeding it into each of the Osprey-100 capture boards.

2.   Software Requirements

Windows NT Workstation 4.0 is installed as the operating system on the GCS Processor. The software driver that accompanies the Osprey-100 capture cards must be installed. Providing both streaming video and still imagery to warfighters requires additional software.

a.   *RealProducer*

Streaming video requires encoding a standard video signal into a digital stream for transmission on the network. RealProducer G2 from RealNetworks is a commercially available encoder and operates as a stand-alone application. It was selected because of its widespread commercial use, has been determined to deliver the highest quality imagery on the market, and it is free to use for evaluation purposes. [Ref 5]

b.   *CapturePRO*

Capturing still imagery requires capturing a standard video signal and converting it to a digital image. CapturePRO ActiveX from Pegasus Software control is a commercially available programming toolkit for embedding video acquisition in Windows programs. As an ActiveX control it provides the methods and properties that are needed to preview and capture imagery. Pegasus CapturePRO was selected due to the industry-leading reputation of Pegasus Software in the imaging tool arena, and because a free trial version of the ActiveX control for CapturePro was available.

E.   STREAMING VIDEO

With RealProducer, providing streaming video content is easily accomplished using the RealMedia Recording Wizard. The operator starts the program, which automatically starts the wizard, and follows the directions.

1.   New Session

The first requirement is to select the type of media clip that it is to be created, which in our case is a live broadcast (Figure 5.3).
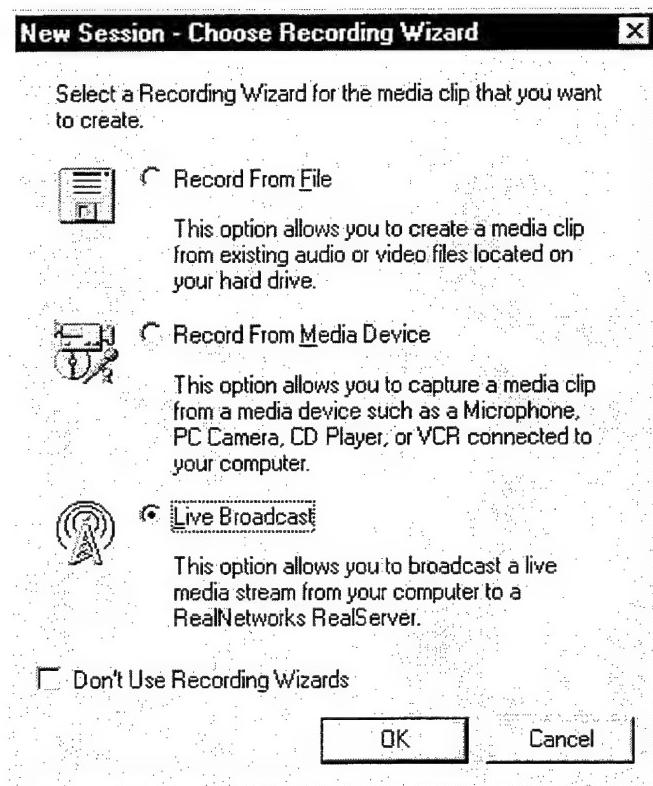

Figure 5.3: Recording Wizard – New Session

39

2.   Input Source

Next, the type of media to capture and source of this media must be set. In our
case the type of media is video, and the source is set to one of the Osprey-100 video
capture cards (Figure 5.4).
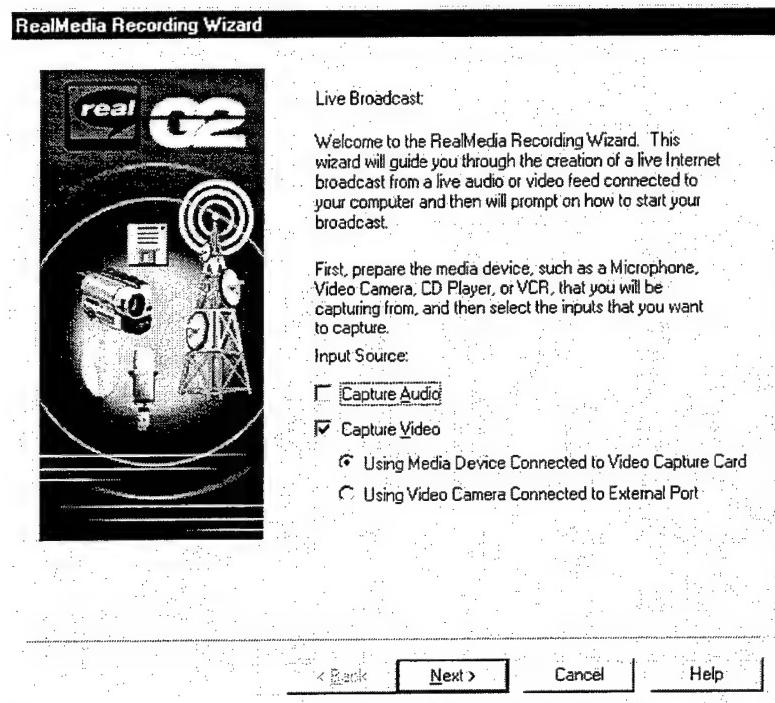

Figure 5.4: Recording Wizard – Input Source

3. Title and Author

A title and author of the broadcast is also set (Figure 5.5).
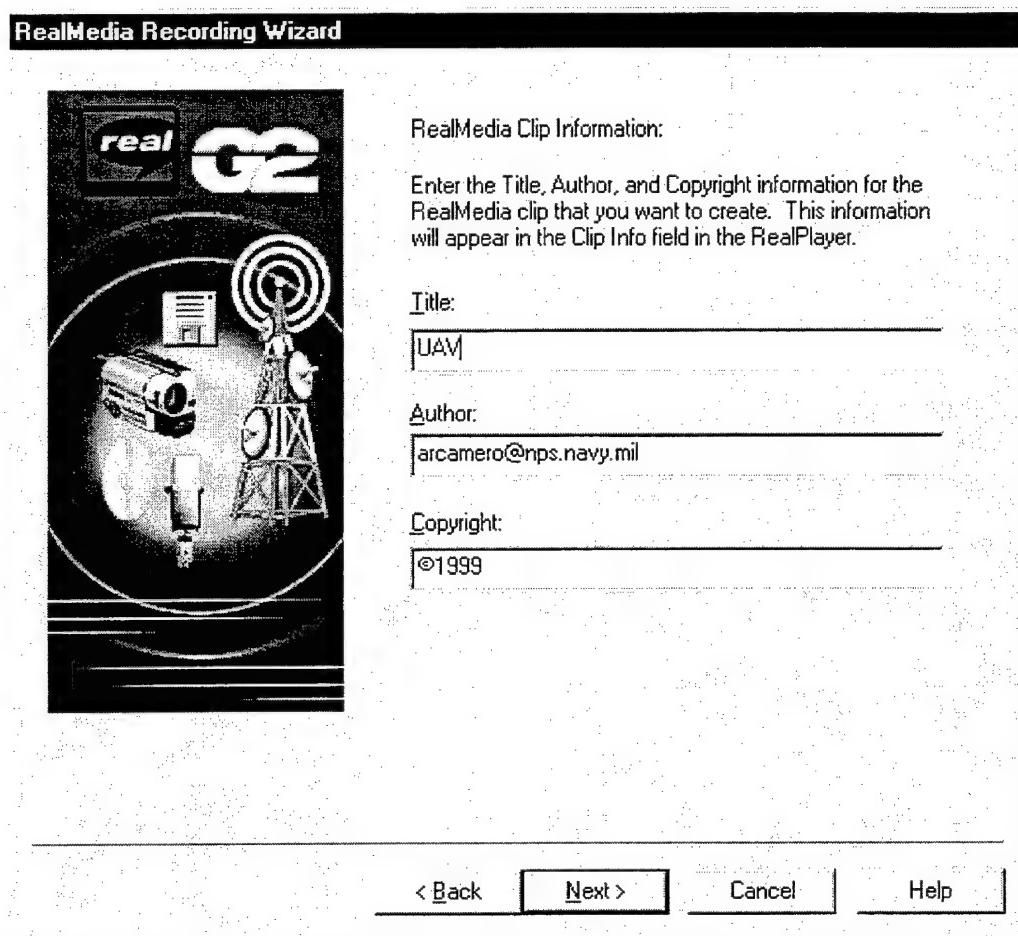

Figure 5.5: Recording Wizard – Title and Author

4. File Type

The file type for the media clip must be selected. The options for file type are
SureStream and single rate. SureStream is a scalable format that compresses multiple
connection bandwidths into a single stream that dynamically adjusts data flow to
changing line conditions. Single rate will provide only a single bandwidth of streaming
video from a web server. In our implementation, file type was set to single rate since
only one video stream of constant bandwidth was demonstrated (Figure 5.6).
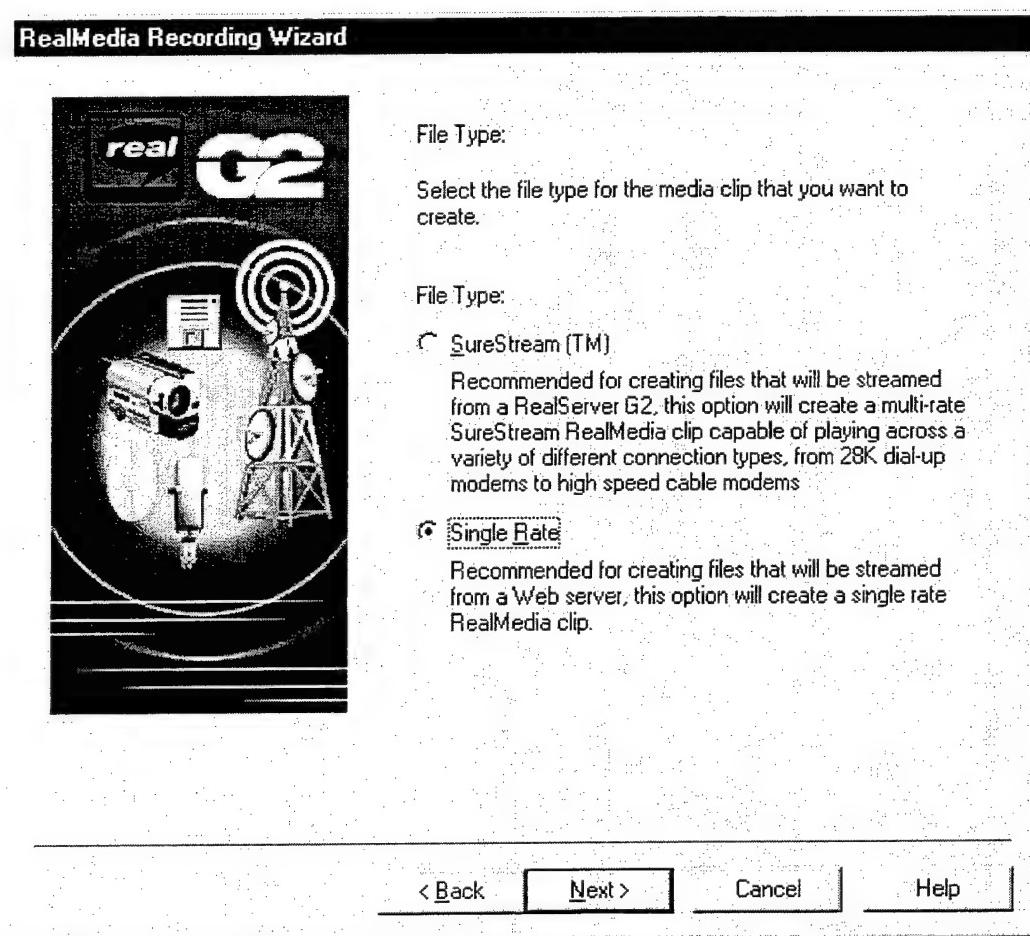

Figure 5.6: Recording Wizard – File Type

5.   Target Audience

The target audience data rate setting effects the image quality and frame rate of the digitized video stream, but must be set within available bandwidth limitations. Various target audience data rate settings were tried, with a determination that this must be set at no greater than single rate ISDN to ensure that the maximum tested bandwidth of 115 kbps between the GCS Processor and Server is sufficient (Figure 5.7).
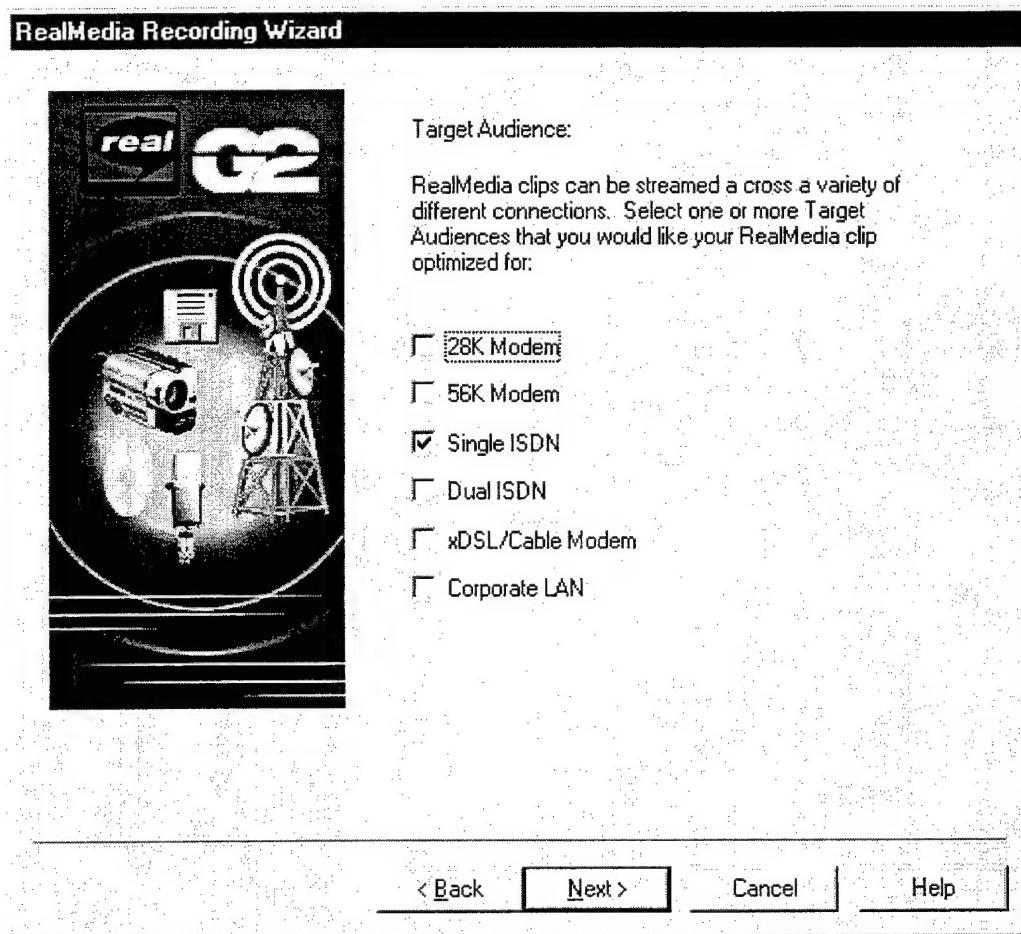

Figure 5.7: Recording Wizard – Target Audience

6. Video Quality

It was also determined that in order to maximize image quality, the video quality setting should be set to slide show (Figure 5.8).
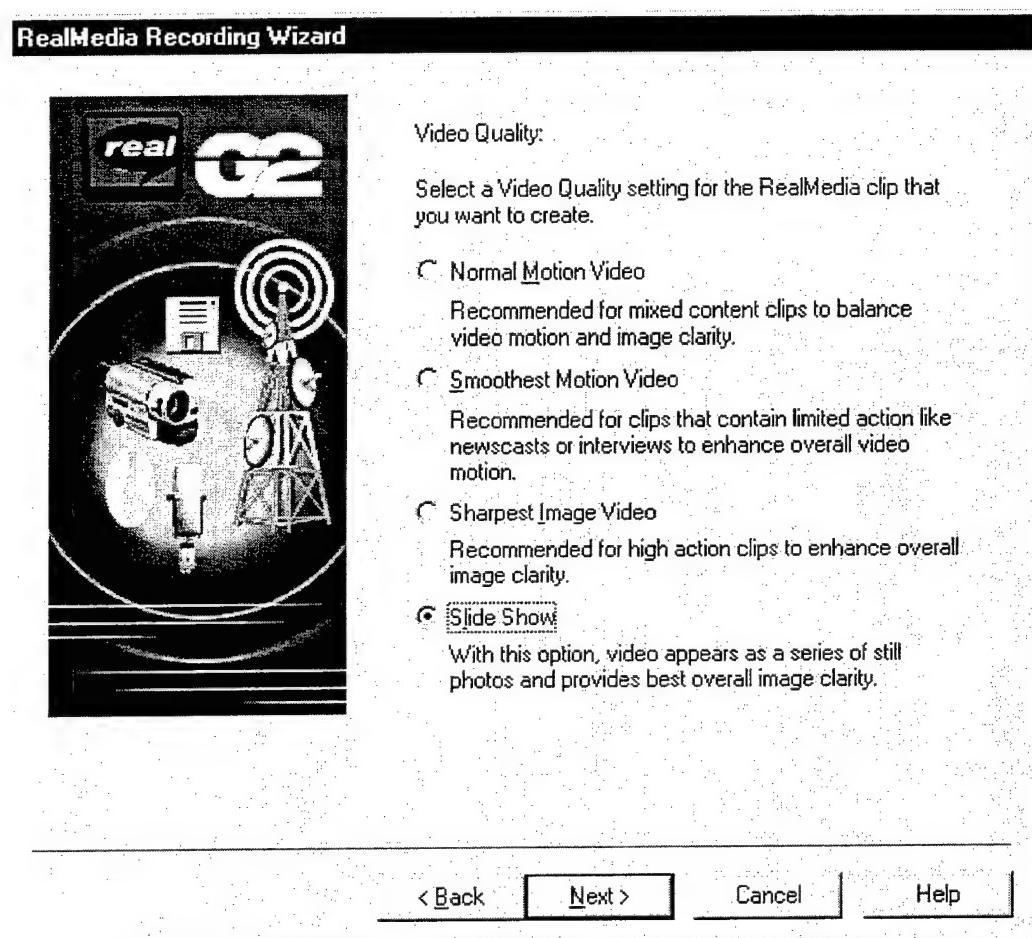

Figure 5.8: Recording Wizard – Video Quality

7.   Server Settings

To complete the configuration of RealProducer G2, the media server that the live
video stream will be broadcast from must be identified. This involves specifying the
name and port number of the server, a filename used to reference the live video stream,
and a username and password necessary to login into the server. In our implementation,
the RealServer is "ratbert", the port is "4040", the filename used is "live", and the
username and password are both "utips" (Figure 5.9).
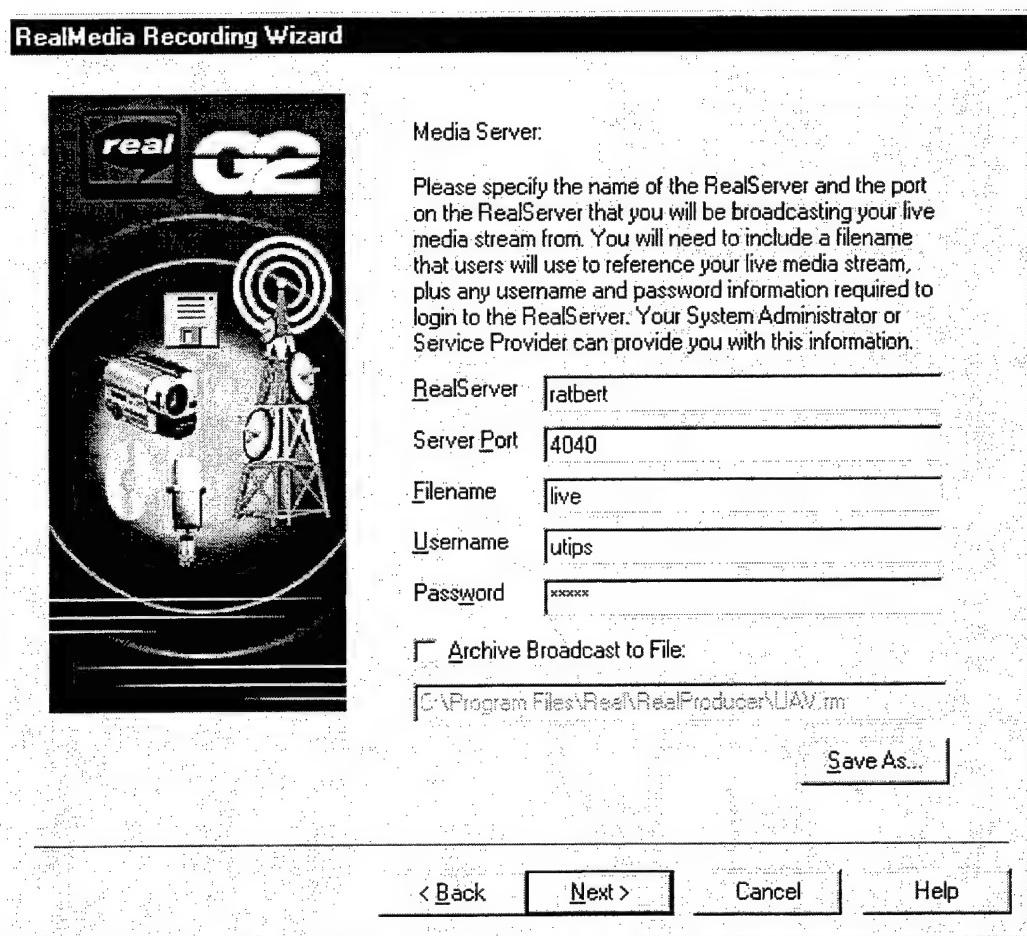

Figure 5.9: Recording Wizard – Media Server Settings

8.   Configuration Complete

When configuration of RealProducer G2 is complete, the main application
window (Figure 5.10) is displayed from which the user can start and stop the streaming
process and make configuration changes.
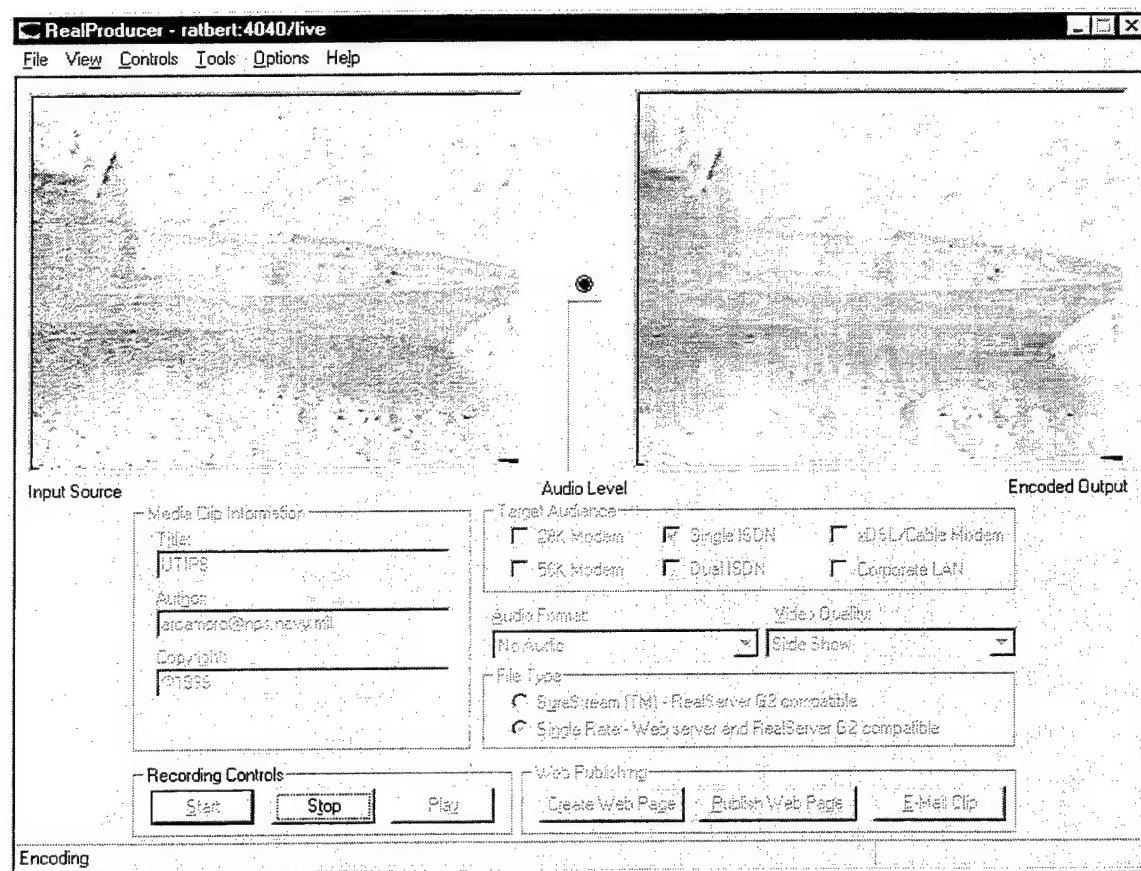

Figure 5.10: RealProducer G2 Application Window

F. STILL IMAGERY

Unlike video streaming, there is no ready to run commercial software solution for capturing still imagery. Rather, the CapturePRO ActiveX control is embedded in an application developed by the authors for this purpose. An Osprey-100 capture board provides the video source for capturing imagery and must be first be configured for operation.

1. Capture Source Settings

First, capture source settings must be initialized. This is done when the Track Injection and Image Capture System application is started. The video input, signal specification, and capture board must be selected. As shown in Figure 5.11, it is Composite 1, NTSC-M, and Board 1.
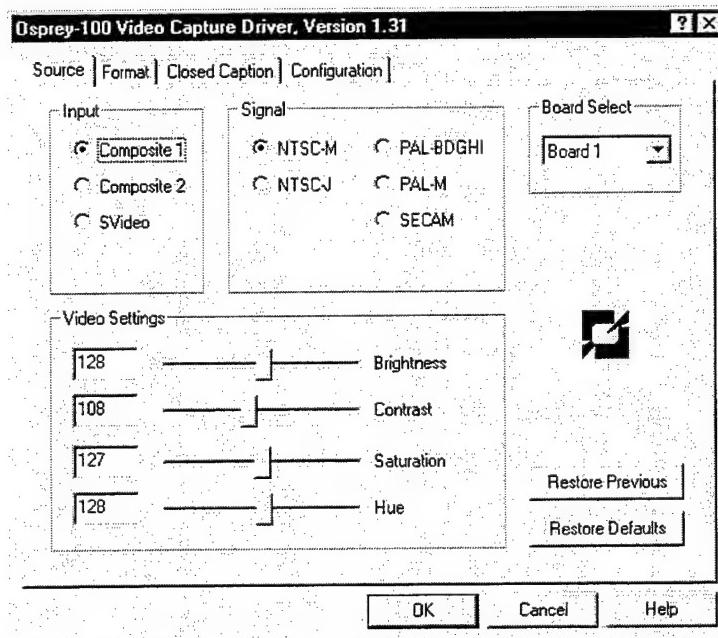

Figure 5.11: Opsrey-100 Video Capture Driver Source Settings

2. Capture Format Settings

Second, the color format and video must be set. As shown in Figure 5.12, they are RGB15 and 320x240.
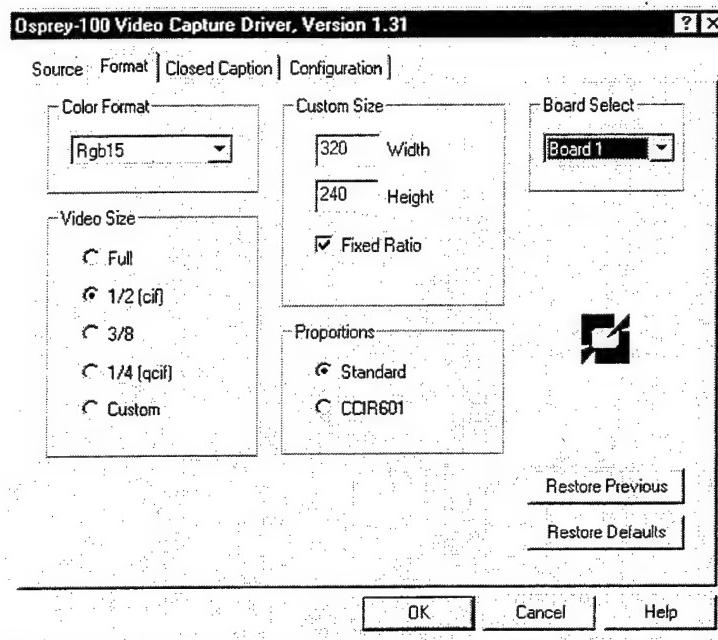

Figure 5.12: Opsrey-100 Video Capture Driver Format Settings

3. Configuration Complete

With the capture settings configured, the main application window (Figure 5.13) is displayed, and imagery is visible. To capture an image, the operator presses the "Capture Frame" button. Pressing "Adjust Video" allows the operator to adjust the video settings using the dialog shown above in Figure 5.11. Appendix A contains the code used to create the user interface.
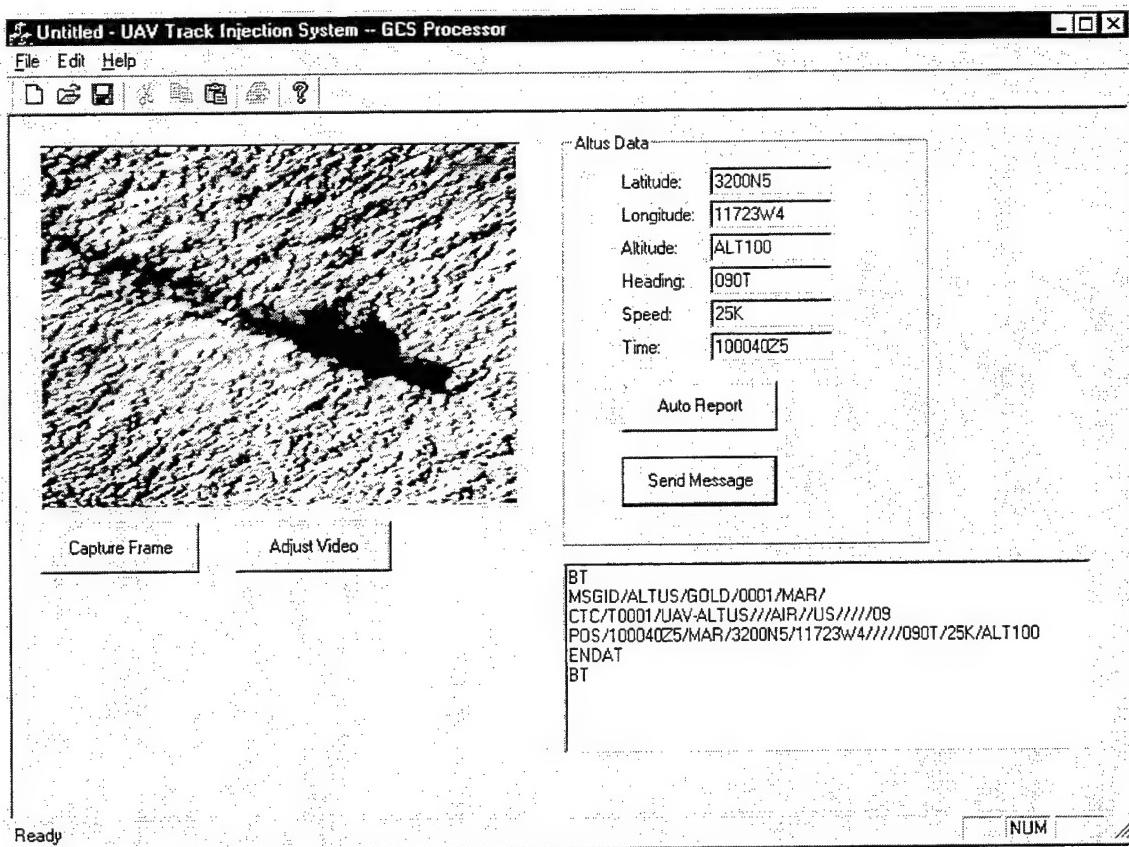

Figure 5.13: Track Injection and Image Capture Application Window

4. Capturing Still Imagery

Imagery without time and position data is not of much value to warfighters. Therefore when an image is captured, there must be a method by which this data is associated with the captured image. To accomplish this, when the operator presses the

"Capture Frame" button, the track number, the time of capture, and the position of the UAV are recorded. This data is used to generate an OTG contact report for the image and is injected into GCCS, additionally, this data is recorded in an imagery database for later retrieval using a web browser.

a. Track Number

A unique track number is assigned to the image. This track number identifies the image for correlation between GCCS and the image database.

b. Time of Capture

The date and time of capture is recorded and is used to generate a unique file name for the image and is used for the time data on the OTG message.

c. Position

As discussed in Chapter IV, position data is derived from UAV telemetry data. This serves as an approximate position of the reported image. Following capture, the next immediate telemetry packet is read and processed. This data is used as the position of the image in the report as there is currently no means of extrapolating the actual position of the image.

d. Process

The image is converted to a JPEG format image that is saved, over the network connection, on the server. The directory in which it is saved is read-only accessible to web browsers. The file name, track number, time, and position data are used to build an SQL statement that updates the imagery database.

G. DATA TRANSFER

Streaming video and still imagery are sent to the domain server using the same TCP/IP connection discussed in chapter IV. The server is then responsible for distributing imagery to requesting clients.

1. Streaming Video

RealProducer does not have the capability of serving "live" content to requesting clients therefore additional software is required. RealServer G2, also from RealNetworks and also free for evaluation purposes, provides the services necessary to serve streaming video. RealServer is installed on the domain server. The purpose of this is twofold: to minimize bandwidth demand and to maximize GCS Processor performance.

a. *Bandwidth*

For every client connection to RealServer, a separate – and duplicate – data stream is sent. The serial connection between the GCS Processor and the domain server is just not fast enough to support this network demand and would be quickly overwhelmed with network traffic. A network connection is required for clients. The domain server is connected to an Ethernet backbone and is the logical point from which to serve streaming video.

b. *Performance*

Capturing and encoding video is a CPU intensive task. Thus measures must be taken to minimize the amount of processing required by the GCS Processor. Locating RealServer on the domain server releases the GCS Processor from the burden of serving content to users.

2. Still Imagery

Still images, when captured, are sent to the domain server for storage and later retrieval using a web browser. As was the case for streaming video, images are stored on

51

the server to minimize bandwidth demand between the GCS Processor and the domain server resulting from web client requests.

H.   DISTRIBUTION OF IMAGERY

Imagery is distributed using commercially available software. Microsoft's Internet Information Server 4.0 is used to co-ordinate the various data sources to users. These data sources are RealServer G2, which provides the streaming video, and Microsoft's SQL Server 6.5, which provides still imagery content. When viewing the UTI^{2}PS home page (Figure 5.14), the most recently captured image is displayed as well as buttons to the "live" video stream and the imagery database.
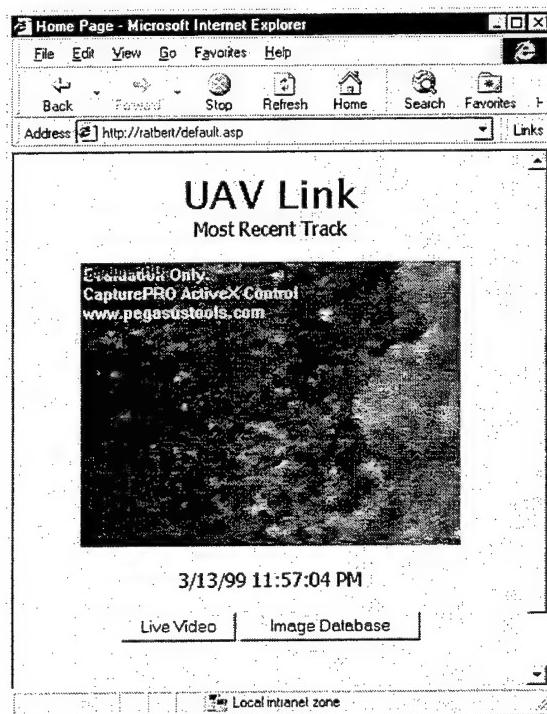

Figure 5.14: UTI^{2}PS Home Page

1.   Streaming Video

With RealServer G2 as the streaming video content provider, RealNetworks' RealPlayer G2 is required to view "live" video and must be installed on client

workstations. When a user requests the "live" feed, a new browser window is created and embedded within the window is the RealPlayer G2 ActiveX control which contains the properties required to receive the "live" video.
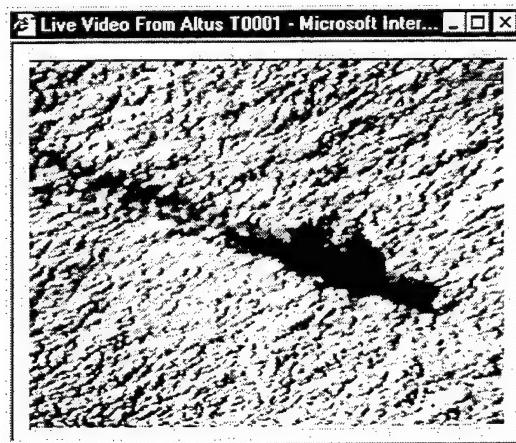

Figure 5.15: Live Video Feed from RealServer

2.   Imagery Database

The imagery database is used to maintain imaging data from the UAV. It is built using Microsoft's SQL Server 6.5. The reason for using SQL Server is that it is easily scalable if network demand increases and that a 120 day evaluation version is freely available. This database contains only one table, the contents of which are: track number, image name, time of contact, latitude, longitude, altitude, and remarks. See Appendix C for the database definition.

By using IIS 4.0 and SQL Server 6.5, retrieving data from the database for presentation using web browsers is easily accomplished using Microsoft's VBScript. The Image Database web page (Figure 5.16), when retrieved, executes a script on the server that retrieves imagery data from SQL Server and is presented to the web client as a web page. Appendix D contains the HTML code for the web pages.

53
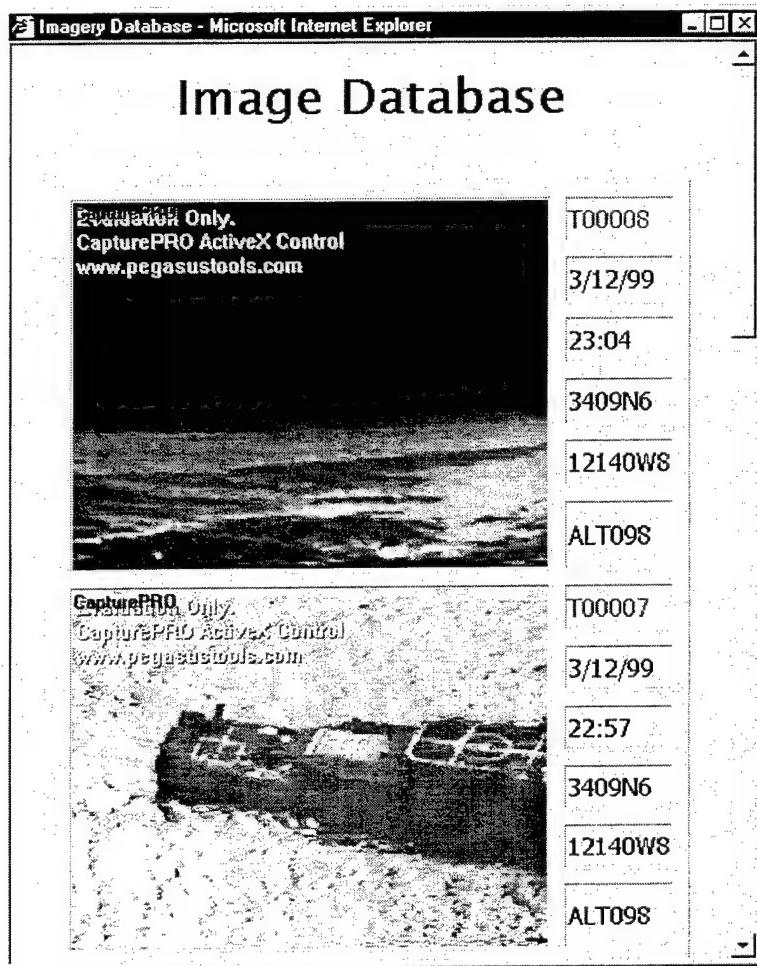

Figure 5.16: Image Database Web Page

I.   SUMMARY

By using low-cost commercially available software it was demonstrated that UAV imagery can be captured and distributed to users over a TCP/IP network. Streaming video in particular is widely available on the Internet and recent advances in this field make the application in our research quite valuable. Capturing still imagery, though incorporating commercially available components, still requires a programmatic solution to provide additional data to correlate imagery with GCCS tracks.

VI. PROOF-OF-CONCEPT DEMONSTRATION

A. INTRODUCTION

This chapter describes the proof-of-concept demonstration for UTI²PS in the
Systems Technology Battle Lab Annex. The purpose of the demonstration is to prove the
viability of distributing UAV telemetry data and imagery to the warfighter. The
remainder of this chapter discusses limitations, the lab simulation, and its configuration.

B. LIMITATIONS

This section discusses three major limitations discovered during the research and
implementation phases of this thesis: a disabled data source, bandwidth available from
the UAV GCS and the NPS STBL, and security considerations.

1. Data Source Disabled

The first GCS software build made UAV telemetry data externally available
through and RS-422 port, however, the current software does not allow telemetry data to
be sent to the external GCS RS-422 serial port. The unavailability of required data from
the port was unknown at the time our research began. Testing by General Atomics
personnel verified that the port itself was functional, but that the port was wired
incorrectly. Further testing revealed that the software module that provides telemetry
data to the serial port was disabled in the current software build to provide other UAV
capabilities and is expected to be corrected with the next software build.

2. Bandwidth Between CIRPAS and NPS

OTG message and imagery routing requires a TCP/IP connection. Personnel in
the GCS access the NPS Campus Area Network (LAN) using POTS dial-up connections
on degraded phone lines. The connection speed, which is typically less than 20,000 bps,
is more than sufficient for routing OTG messages, and is an acceptable rate for the
routing of an occasional still image. Streaming video, even at the lowest encoding rate

55

(28.8 kbps), is not possible without total degradation of the network connection. Multi-link point-to-point in which two phone lines are used in parallel was explored as a solution for increasing the available bandwidth, but with the current phone lines the maximum rate expected is no more than 40,000 bps and therefore is not a feasible solution.

As discussed in Chapter V, the optimum configuration for Real Encoder is single-channel ISDN in slide show mode. This provides updated content once per second with an acceptable resolution of 320x240 pixels. With the additional requirements for OTG messages and still images, testing reveals that 115,000 bps is the practical minimum bandwidth required. Dual-channel ISDN or 128K Frame Relay between CIRPAS and NPS is required for field testing all features.

3. Security Concerns

The ultimate goal of this research is to distribute UAV track data to GCCS users in the fleet in real time. To do this, OTG messages must be routed from the unclassified GCS processor to a secret track information database connected to the SIPRNET. Without a satisfactory security apparatus, testing with a live GCCS server is not possible.

C.   LABORATORY SIMULATION

With the limitations described above, an overall "live" systems test was not possible, so elements of the system architecture were simulated as shown in Figure 6.1.
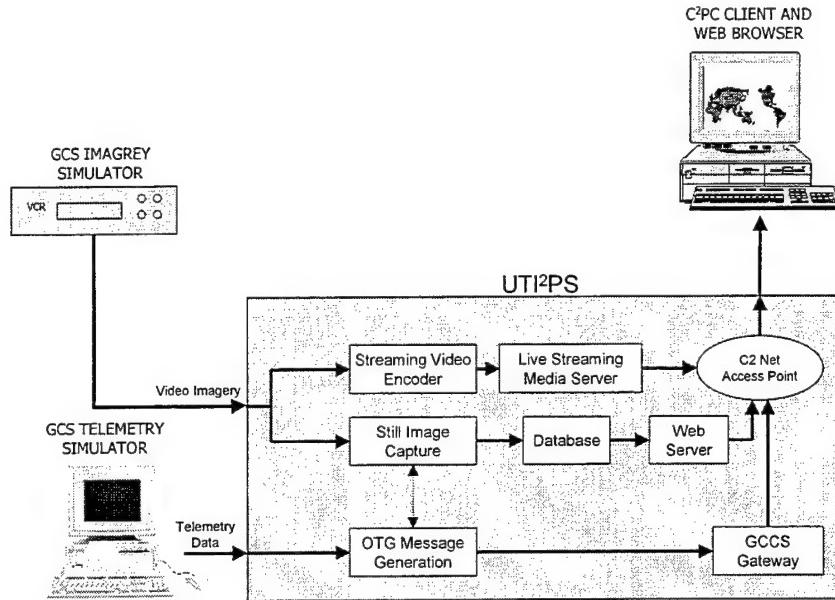

Figure 6.1: Simulated UTI^{2}PS Architecture

1.   GCS Telemetry Data

UAV telemetry data from the GCS is simulated using a telemetry data generator program (Figure 6.2) developed by the authors, which generates telemetry data packets in the same format as specified for the GCS. The user enters a starting point in latitude and longitude, and parameters for course, speed, and altitude. Actual telemetry data packets are generated at a rate of 10Hz and sent to the GCS RS-422 serial port. The purpose of the generator is to simulate sending UAV data from the GCS with which to test the OTG generation algorithm on the GCS processor. The code used to create the GCS telemetry simulator is contained in Appendix B.

57
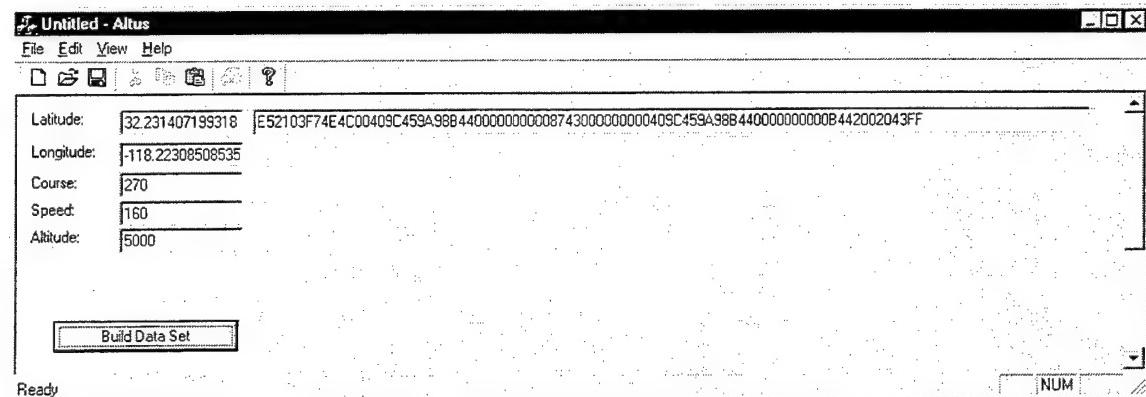

Figure 6.2: Telemetry Packet Generator

2.   GCS Imagery Data

CIRPAS provided a VHS tape containing UAV imagery with which we tested still image capture and streaming video encoding using a VCR. Both the GCS and a VCR use standard NTSC analog video signals.

3.   Remote Connection

Bandwidth requirements were tested using a null-modem serial cable and a remote access server. This allowed the flexibility of testing line speeds from 19,200 bps to 115,000 bps to determine the effects of available bandwidth with required bandwidth. Testing with conventional modems was impractical given the condition of the phone lines.

4.   GCCS Track Information Database

Inter-National Research Institute's (INRI) C^2PC Suite for Windows NT is used as a stand-alone GCCS track information database and COP. With the C^2PC Gateway application we are able to test the processing of OTG messages generated by the GCS processor as well as display tracks on the GCCS COP.

58

D.   CONFIGURATION

For the proof-of-concept demonstration, four Pentium II based computers were used in a networked single master domain environment. The overall actual and simulated architectures were presented earlier in Figures 3.3 and 6.1. Figure 6.3 shows how each of the links, nodes, and inter-node translations were effected and how each computer in the simulation is configured. Windows NT 4.0 was selected as the operating system because of familiarity from previous course work, programming experience, and the availability of free trial editions. Microsoft Internet Explorer 4.0 and RealNetworks Player G2 are installed on all computers. TCP/IP and NetBEUI are installed as the network transport protocols.
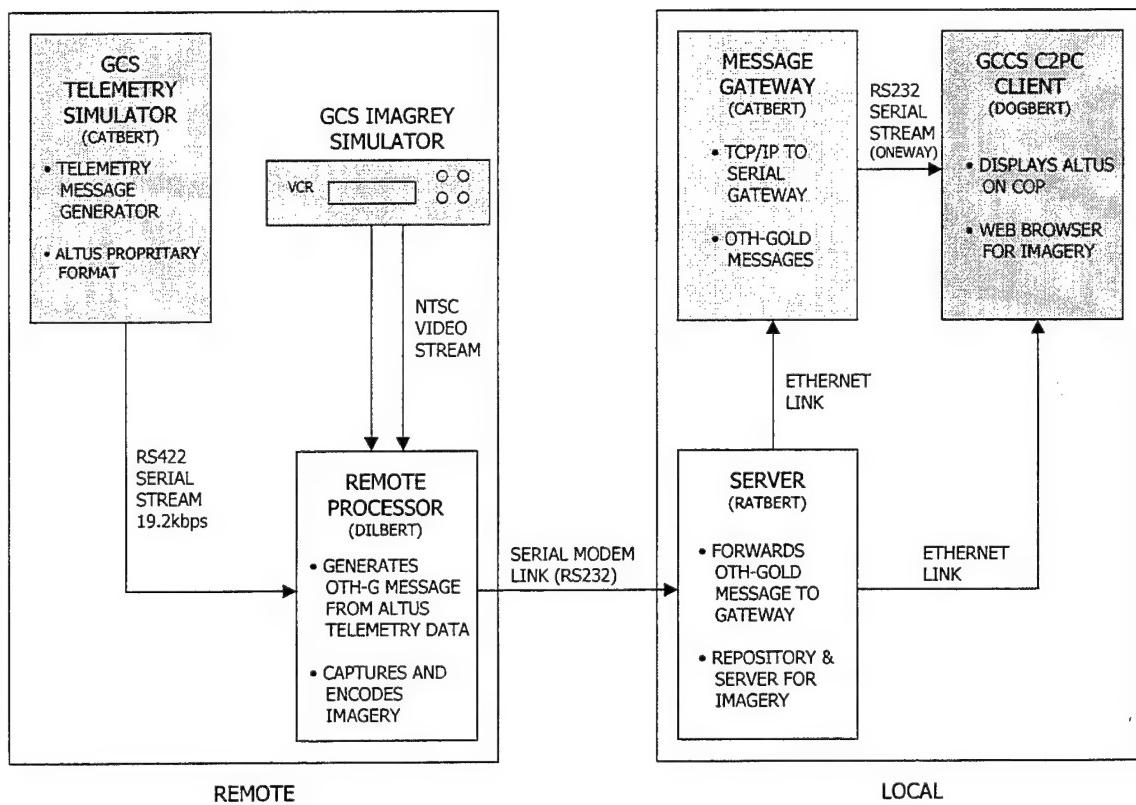

Figure 6.3: Proof-of-Concept Architecture

59

1. Network Server

The first computer (Ratbert, Figure 6.4) is configured as a primary domain controller for the UTIPS domain using Windows NT Server 4.0. Internet Information Server 4.0 provides WWW services with SQL Server 6.5 providing database support. RealNetworks Server G2 provides streaming media content. RAS is installed to support dial-up and direct connect serial connections between the GCS processor and the network. The network is visible to the remote connections and IP forwarding is enabled. WINS and DNS were installed to allow the use of fully qualified domain names without having to manage multiple host tables.

2. GCS Processor

The second computer (Dilbert, Figure 6.5) is configured as the GCS processor. RealNetworks Producer G2 encodes the video signal provided by one of two video capture boards. The second video capture board is used by the Pegasus CapturePro 1.02 ActiveX control under the framework of the UAV Track Injection and Image Capture Application for still image capture. The RS-422 serial port is for receiving data from the Telemetry Data Generator. Dial-up networking is installed for connectivity to Ratbert and the UTIPS domain.

4. Telemetry Generator and GCCS Relay

The fourth computer (Catbert, Figure 6.7) was configured as the telemetry packet generator and GCCS relay. As a packet generator, telemetry data packets are sent to an RS-422 serial board. GCCS relay runs as an independent process that "listens" for OTG messages on the network, messages, when received are routed to an RS-232 serial port.

E. RESULTS

The architecture, simulated in the lab (Figure 6.8), successfully demonstrated the viability of injecting track data and distributing imagery into a command and control network. However, the availability of bandwidth between the GCS processor and the domain server places a significant constraint on the level of service. Streaming video has the greatest demand for bandwidth and, if not managed properly, can block the transmission of OTG messages and captured still imagery.
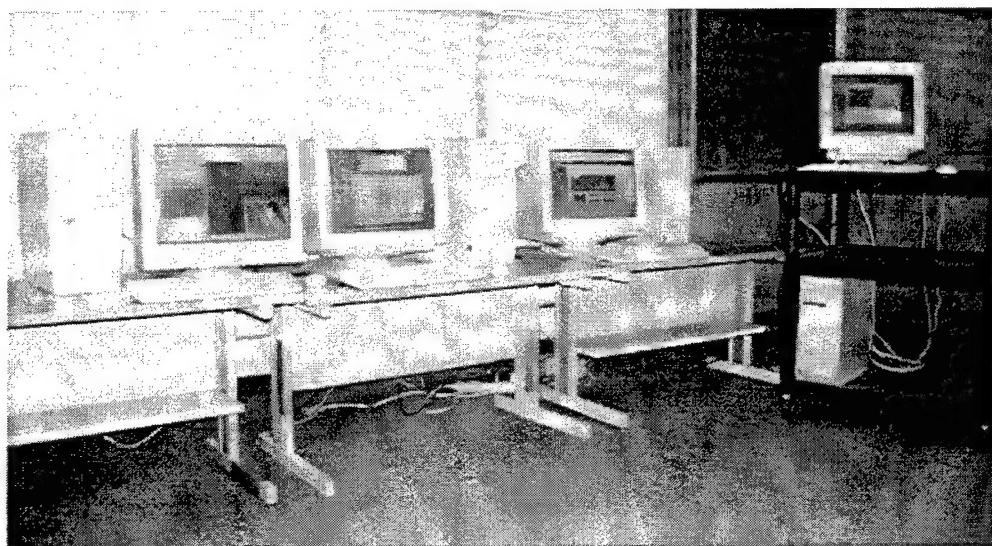

Figure 6.8: Laboratory Simulation

1. Telemetry

Altus UAV telemetry packets are properly translated to OTG contact reports and are routed correctly to the C^2PC Gateway and upon processing are displayed on the C^2PC COP. However, three issues need to be addressed.

a. OTG Message Queue

The C^2PC Gateway does not immediately process OTG messages upon receipt. Received messages are held in a queue and message processing does not occur

until another message is received. With the Track Injection and Image Capturing Application running in "auto" mode, OTG messages are sent every 20 seconds. This results in a minimum 20-second latency before the track is updated. This appears to be a design flaw of the C^{2}PC Gateway itself and with frequent OTG traffic is not an issue, however with infrequent messages, there can be a substantial delay before the message is processed.

b. Time Resolution

Time, which is resolved to the minute, impacts the maximum frequency in which a track's position may be updated. C^{2}PC will process and discard position reports with the same date-time group and track number. In the "auto" mode with OTG messages sent every 20 seconds, the first message with a new date-time group will cause the track to be updated, the following reports will be ignored. Therefore, the maximum track update frequency is one per minute.

c. Position Resolution

Latitude and longitude in the OTG message have a resolution to the nearest minute. Thus, the actual position of the Altus UAV, as well as any tracks reported through the imaging subsystem, will be rounded to the nearest minute in the OTG contact report for a position error of 0.7 nautical miles near the equator. Because UTI^{2}PS is not designed to be a targeting system, the impact is marginal.

2. Streaming Video

Streaming video, though compressed, places the greatest demand on bandwidth. Using standard serial ports for connectivity between the GCS processor and the domain server, the maximum line speed available is 115,200 bps. With this constraint, best performance as measured in terms of frame rate and video quality was obtained with the following settings: 320x240 resolution, dual ISDN/slide show for an encoding rate of 82

kbps and a frame rate of 1.2 frames per second. Without dual channel ISDN this is an unrealistic speed.

Reducing the line speed constraint to 57,600 bps requires setting the target audience to 28.8K modem results in an encoding rate of 20 kbps and a frame rate of 0.3 frames per second. This leaves sufficient overhead to send OTG messages and still imagery. With the quality of phone lines at CIRPAS lacking, even a multi-link connection does not provide sufficient bandwidth. A bigger pipe between the GCS processor and the domain server is needed.

3. Still Imagery

Capturing still images not only provides the best resolution imagery but also injects a new track into GCCS marking an approximate location of the image. With this feature, GCCS users are alerted that the UAV has found a contact of interest. However, as there is no means of capturing the actual position of the contact, the reported position is that of the UAV at the time of capture. Without the orientation of the payload camera this results in a significant and unknown error that is wholly dependent on the altitude of the UAV.

Bandwidth for imagery is a consideration, but the Track Injection and Image Capturing Application prevents users from overloading available bandwidth by blocking capture requests while imagery is being sent.

F. SUMMARY

The UTI^{2}PS simulation successfully demonstrates the value of UAV track injection and image capturing. With off-the-shelf component it shows that it is feasible to provide UAV sensor data to shooters in the fleet at low cost.

VII. CONCLUSIONS AND FURTHER RESEARCH

A. CONCLUSIONS

While it is clear that UAVs have rapidly developed to fill critical reconnaissance needs, the CONOPS for using UAVs and underlying command and control structure has not been able to keep pace to fully utilize these new advances. This is primarily due to a lack of UAV connectivity to modern Command and Control systems. This thesis has demonstrated through a proof-of-concept laboratory implementation, how UAV telemetry information can be viably used to inject real-time tracks of a UAV's position into the Global Command and Control System's (GCCS) Common Operational Picture (COP). Methods of presenting imagery from a UAV have also been demonstrated, including both near-real-time streaming digital video, and digital still imagery from a live feed or database repository. Ways of incorporating telemetry along with digital imagery was also shown, including the injection of tracks within the GCCS COP in order to mark the location of corresponding images of interest.

The technologies developed utilize common-off-the-shelf (COTS) software and hardware, as well as open standards, to as great an extent as possible. Due to the proprietary nature of the Ground Control Station (GCS), a serial RS-422 interface was required for extraction of kinematics telemetry data. A serial RS-232 interface was required for injection of OTG messages into the GCCS C^2PC gateway. With the exception of these serial interfaces, a network-based architecture was used in order to provide high levels of availability, scalability, compatibility, and flexibility. Ideally, a network-centric system where the UAV telemetry and imagery sensors are networked directly to the Command and Control systems would be desired due to the elimination of potential bottlenecks and single points of failure. Although not currently possible, this approach should be pursued as Ground Control Stations and Command and Control systems evolve.

The CIRPAS Altus UAV was utilized as a test-bed for the development of the UTI^{2}PS system, and can subsequently be used as a research tool for the evaluation of evolving UAV Command and Control doctrine. CIRPAS also operates other aircraft, including the Pelican Optionally Piloted Vehicle (OPV) and recently acquired Predator UAV, which can also be used with the UTI^{2}PS system for further research and evaluation.

B.   RECOMMENDATIONS FOR FURTHER RESEARCH

Due to limitations discovered and documented during the research and implementation of this thesis, a "live" demonstration of the UTI^{2}PS system was not possible, although the viability of the system was demonstrated through a laboratory simulation. These limitations are prime areas for further research along with other recommendations that follow.

1.   Verification of GCS RS-422 Port Telemetry

As was previously discussed, in the GCS software build available at the time of this thesis, the software module that provides telemetry data to the serial RS-422 port was disabled. It is expected that this will be corrected in the next software build, which is scheduled for installation in April 1999. This should be verified for proper operation after confirmation of the re-enabling of this feature. Then a demonstration of UTI^{2}PS using telemetry and imagery data from the actual GCS can be conducted.

It was also discovered in our research that the GCS has an Ethernet network connection, the stated function of which is for the loading of new software builds. Although modifications to the GCS software would be required, investigation into the possibility of utilizing this network connection for retrieval of telemetry data warrants further research.

2.   Alternative Communication Means Between the GCS and STBL

It was determined through laboratory simulation that the bandwidth between the GCS and STBL, or other GCCS / SIPRNET injection points, is a limiting factor in the

type and quality of imagery that can be presented. Thus alternative means of establishing a TCP/IP connection between the GCS and injection point should be researched. As was determined through simulation, a single modem, or even dual multi-linked modem connection would provide sufficient bandwidth for telemetry data with an occasional still digital image only, but not streaming digital imagery. To provide streaming digital imagery of moderate quality along with telemetry data for track injection, a minimum bandwidth of 115 kbps was determined to be necessary. Communication via frame relay, dual ISDN, or other means should be investigated and evaluated through proof-of-concept demonstration.

3. Connection of UTI²PS to "Live" GCCS and SIPRNET

Because of security concerns, connection of the UTI²PS system to the "live" GCCS system and SIPRNET was not conducted. In order to route OTG messages from the unclassified proof-of-concept UTI²PS system to the classified GCCS track information database requires special security concerns. A method of doing this was developed in which a one-way serial cable could be used to connect the two systems, ensuring that data could only flow one-way from the lower classified UTI²PS to the higher classified GCCS. This one-way cable mechanism was utilized in the simulated implementation, and is a viable solution. Actual implementation requires further work.

Additional research is also needed before connection to the classified SIPRNET for dissemination of imagery. A satisfactory security apparatus or firewall is necessary to ensure security concerns are satisfied before connecting the two networks of different classification.

4. Time Synchronization of Data using GPS Time

In the proof-of-concept implementation, the time annotated on all imagery and OTG messages is local system time rather than actual GPS time. GPS time is available from the kinematics telemetry data, and thus could be decoded and used for all time

stamps rather than system time. This would be necessary for accuracy in an actual implementation of UTI^{2}PS, and thus warrants further research and development.

5. Annotation / Overlay of Imagery with Telemetry Data

As was previously discussed, when a still digital image is captured, a track marking this contact of interest is injected into the GCCS COP, and recorded along with the image into a database. However, there is no means of capturing the actual position of the contact, as the reported position is that of the UAV at the time of capture. Without the orientation of the payload camera, this results in a significant and unknown error that is wholly dependent on the altitude of the UAV.

The telemetry data, which indicates the actual position of the contact of interest from the payload camera imagery, is available within the GCS. Additional research is required to determine how this data can best be extracted and incorporated within the UTI^{2}PS.

One potential solution would be to obtain the video feed by tapping off of the RGB inputs to the GCS CRTs, which contain the actual position data. A downfall of this solution is that there is also a great deal of additional information displayed on the GCS CRTs that is unnecessary for inclusion in disseminated imagery.

A new closed captioning feature is being incorporated into the GCS that will provide telemetry data for the imagery in an NTSC closed caption format. Since the OPSREY-100 video capture boards are capable of decoding closed-captioned information, this may prove to be the most viable solution.

6. Direct linking of GCCS Track Symbology to Imagery

The proof-of-concept system developed provides tracks of the UAV, as well as tracks indicating contacts of interest, on the GCCS COP. It also provides streaming digital imagery from the UAV, and still digital images of the contacts of interest, along with pertinent telemetry information and a track number that can be correlated to the track on the GCCS COP.

70

The development of a seamless link between the GCCS COP and imagery, so that a user can just click on a track to bring up the corresponding imagery from that location, warrants further research.

7. Upgrade of Existing UAV Architecture

The current architecture used by the UAV and GCS could be improved upon by the incorporation of modern digital imagery technology and a network centric architecture. Ideally, imagery should be captured at the UAV in digital format, such as motion JPEG, and then transmitted along with telemetry data directly to the end tactical user using a network centric architecture. This would provide the highest level of availability and thus should be pursued in further research.
